

Lecture 27:

Under the Hood, Part 1: Implementing Message Passing

**Parallel Computer Architecture and Programming
CMU 15-418/15-618, Fall 2016**

Today's Theme

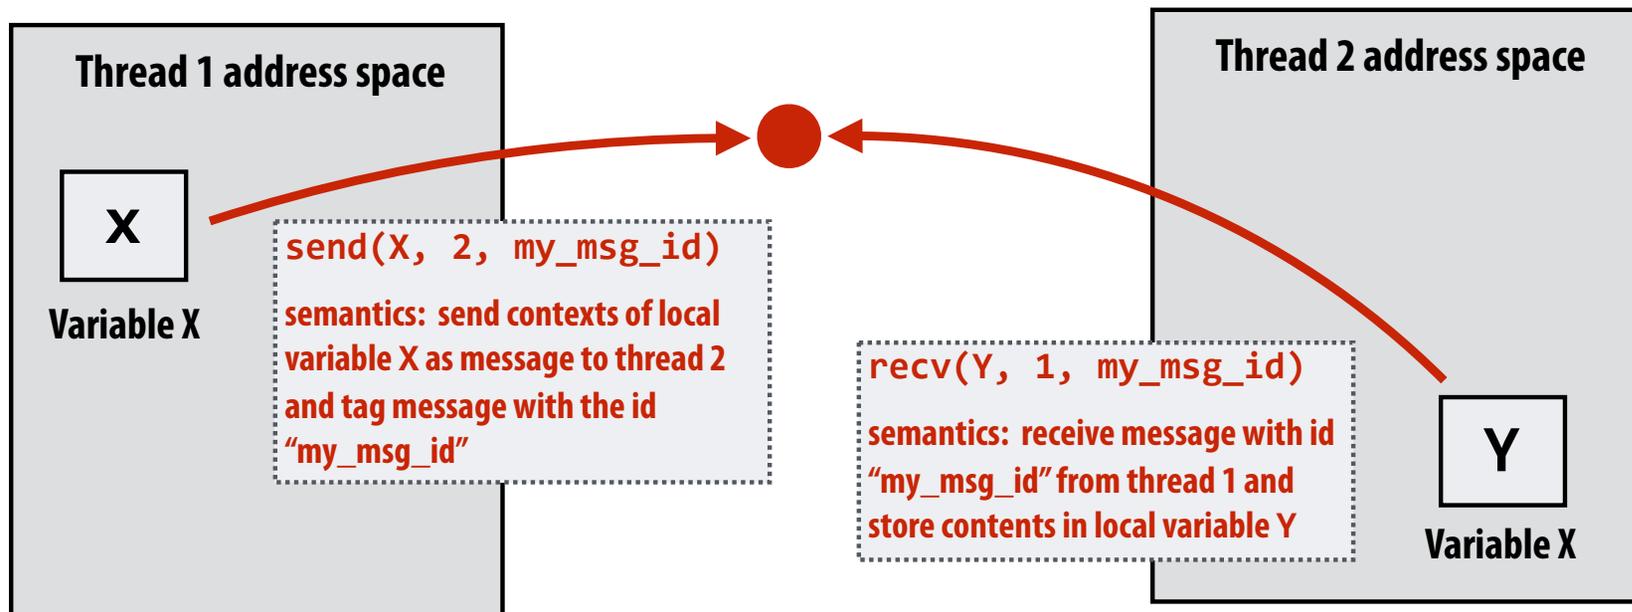

A. Y. OWEN

Through Boy Showing the Engine of His First Car, a 1951 Mercury

THE LIFE PICTURE COLLECTION

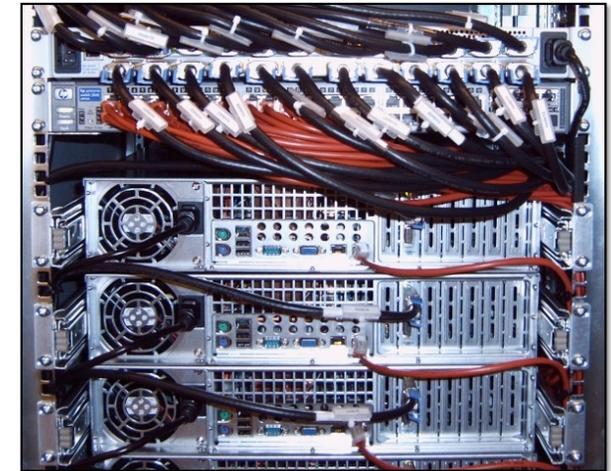

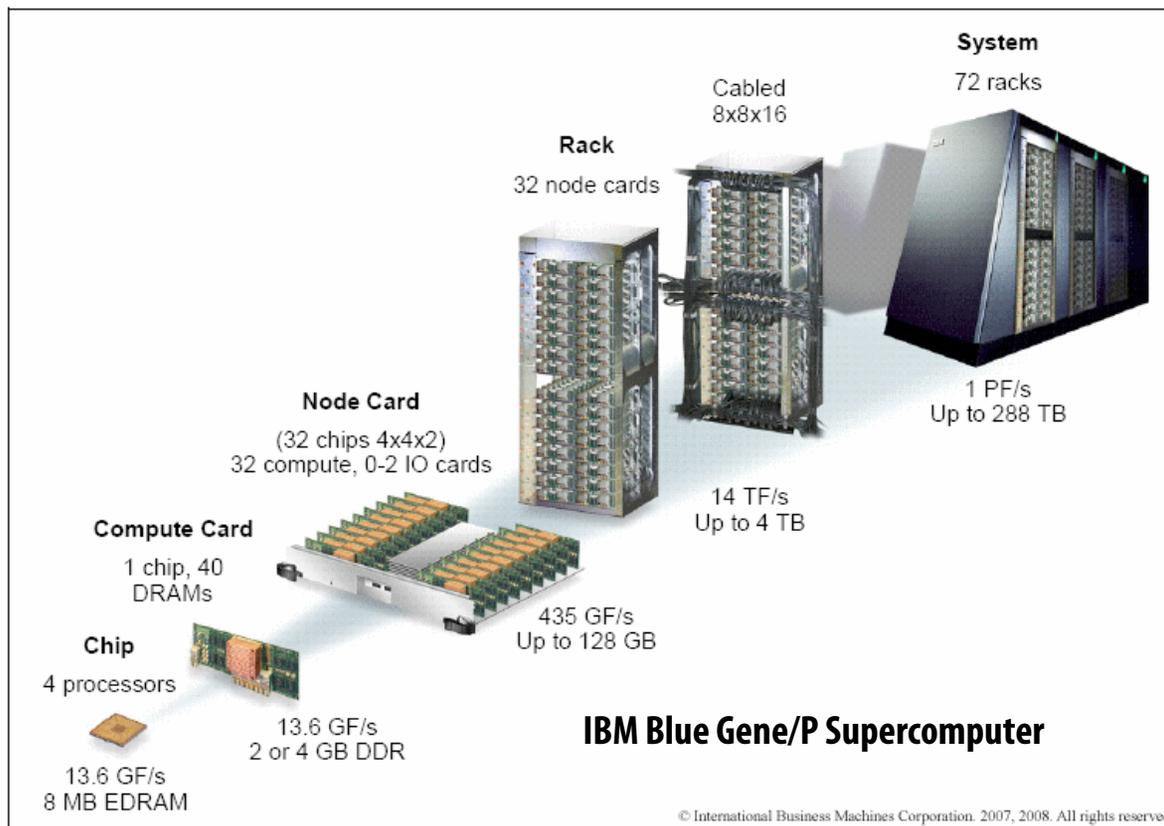

Message passing model (abstraction)

- Threads operate within their own **private address spaces**
- Threads **communicate** by **sending/receiving messages**
 - **send**: specifies recipient, buffer to be transmitted, and optional message identifier (“tag”)
 - **receive**: sender, specifies buffer to store data, and optional message identifier
 - **Sending messages is the only way to exchange data between threads 1 and 2**

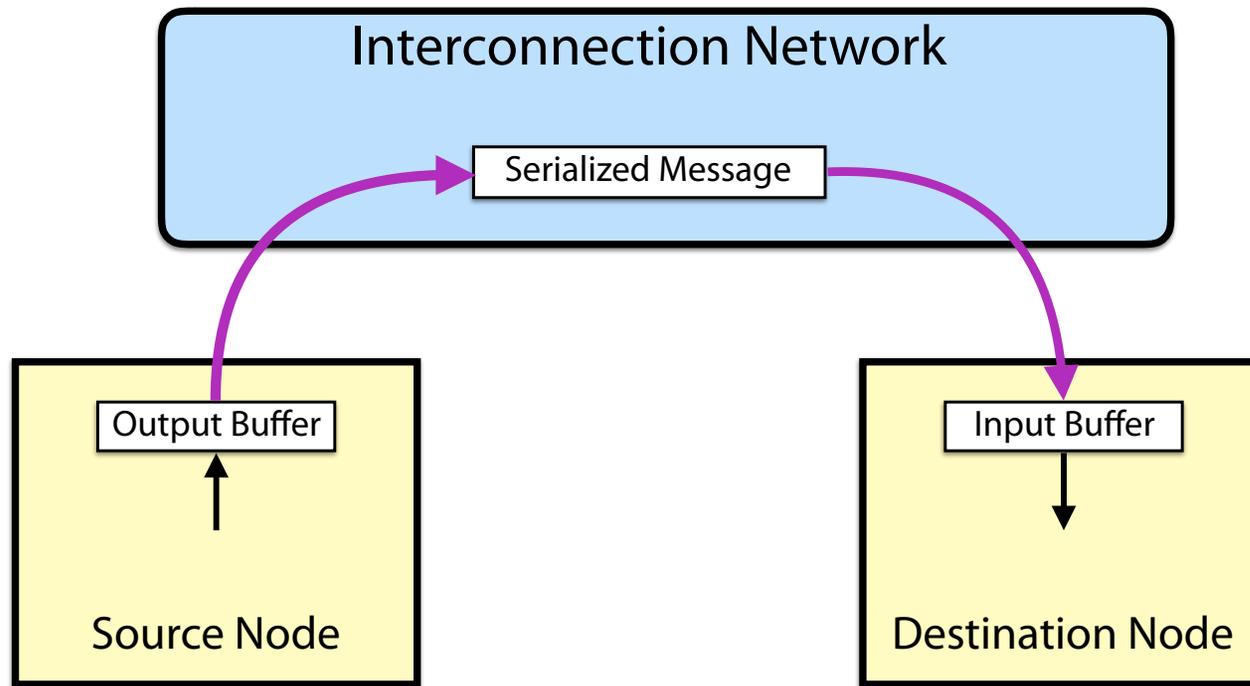

Message passing systems

- Popular software library: **MPI** (message passing interface)
- Hardware need not implement system-wide loads and stores to execute message passing programs (need only be able to communicate messages)
 - Can connect **commodity systems** together to form large parallel machine (message passing is a programming model for **clusters**)

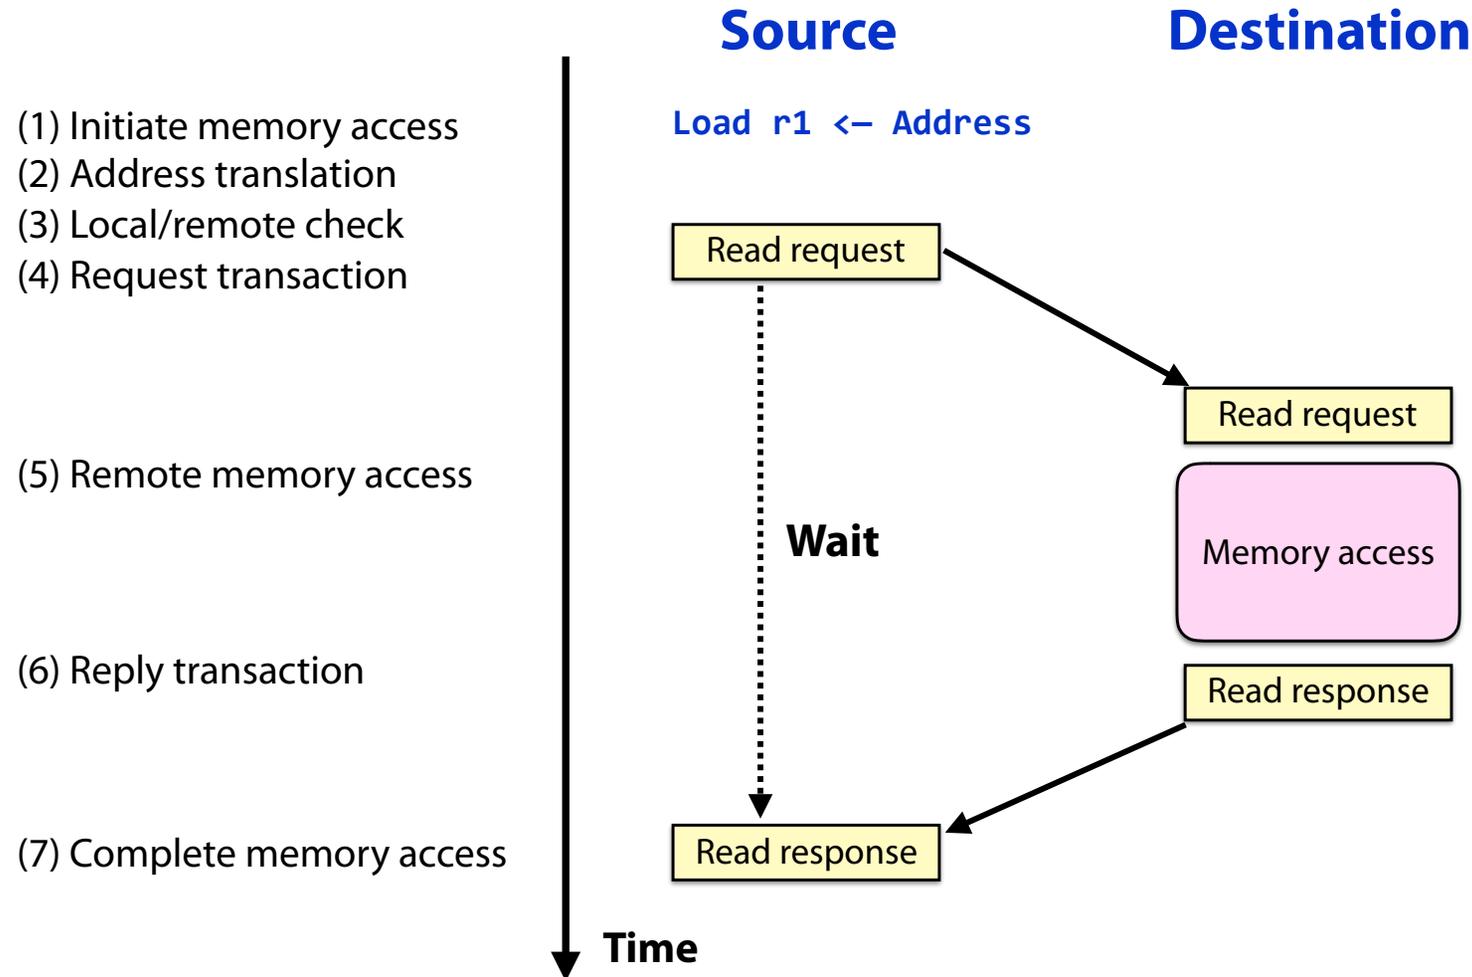

**Cluster of workstations
(Infiniband network)**

Network Transaction

- **One-way transfer** of information from a **source output buffer** to a **destination input buffer**
 - causes some action at the destination
 - e.g., deposit data, state change, reply
 - occurrence is not directly visible at source

Shared Address Space Abstraction

- Fundamentally a two-way **request/response protocol**
 - writes have an acknowledgement

Key Properties of SAS Abstraction

- **Source and destination addresses are specified by source of the request**
 - a degree of logical coupling and trust
- **No storage logically “outside the application address space(s)”**
 - may employ temporary buffers for transport
- **Operations are fundamentally request-response**
- **Remote operation can be performed on remote memory**
 - logically does not require intervention of the remote processor

Message Passing Implementation Options

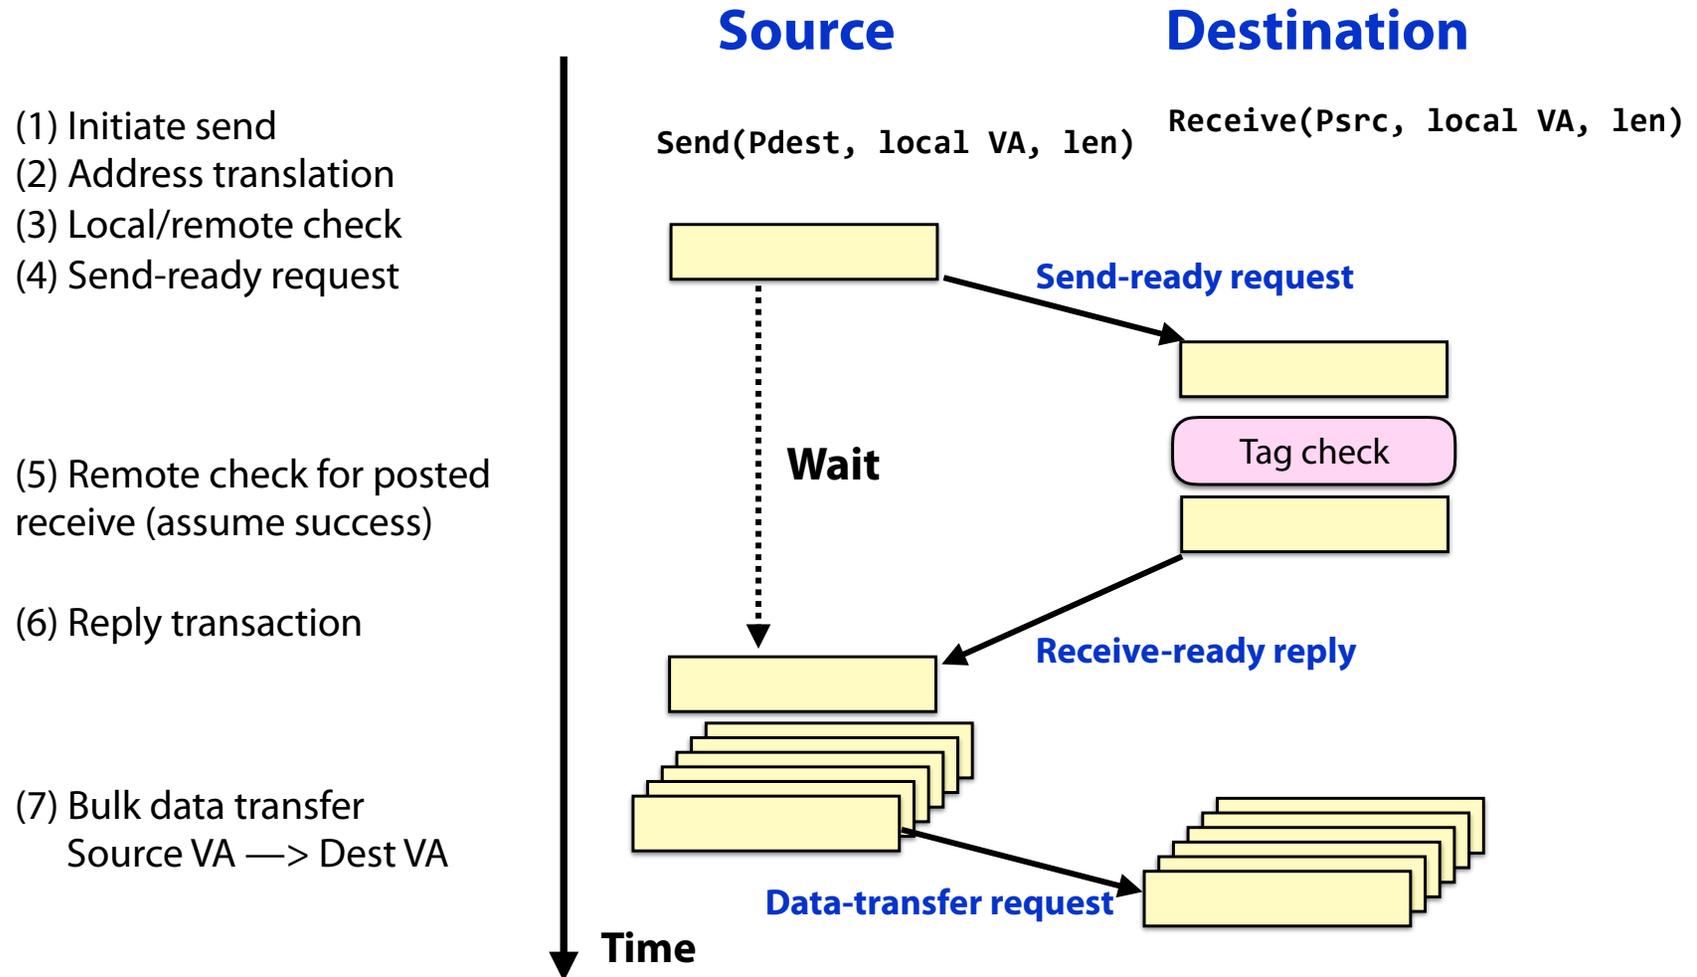

Synchronous:

- Send completes after matching receive and source data sent
- Receive completes after data transfer complete from matching send

Asynchronous:

- Send completes after send buffer may be reused

Synchronous Message Passing

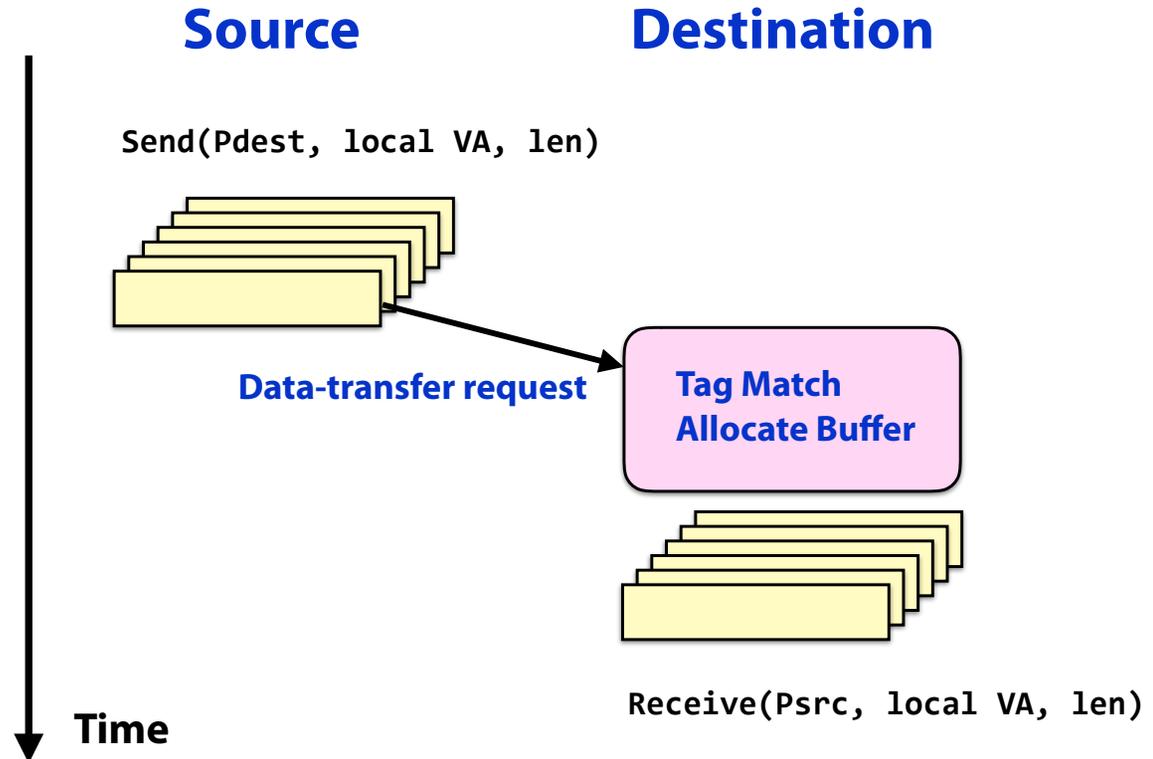

- **Data is not transferred until target address is known**
 - **Limits contention and buffering at the destination**
- **Performance?**

Asynchronous Message Passing: Optimistic

- (1) Initiate send
- (2) Address translation
- (3) Local/remote check
- (4) **Send data**

- (5) Remote check for posted receive; on fail, **allocate data buffer**

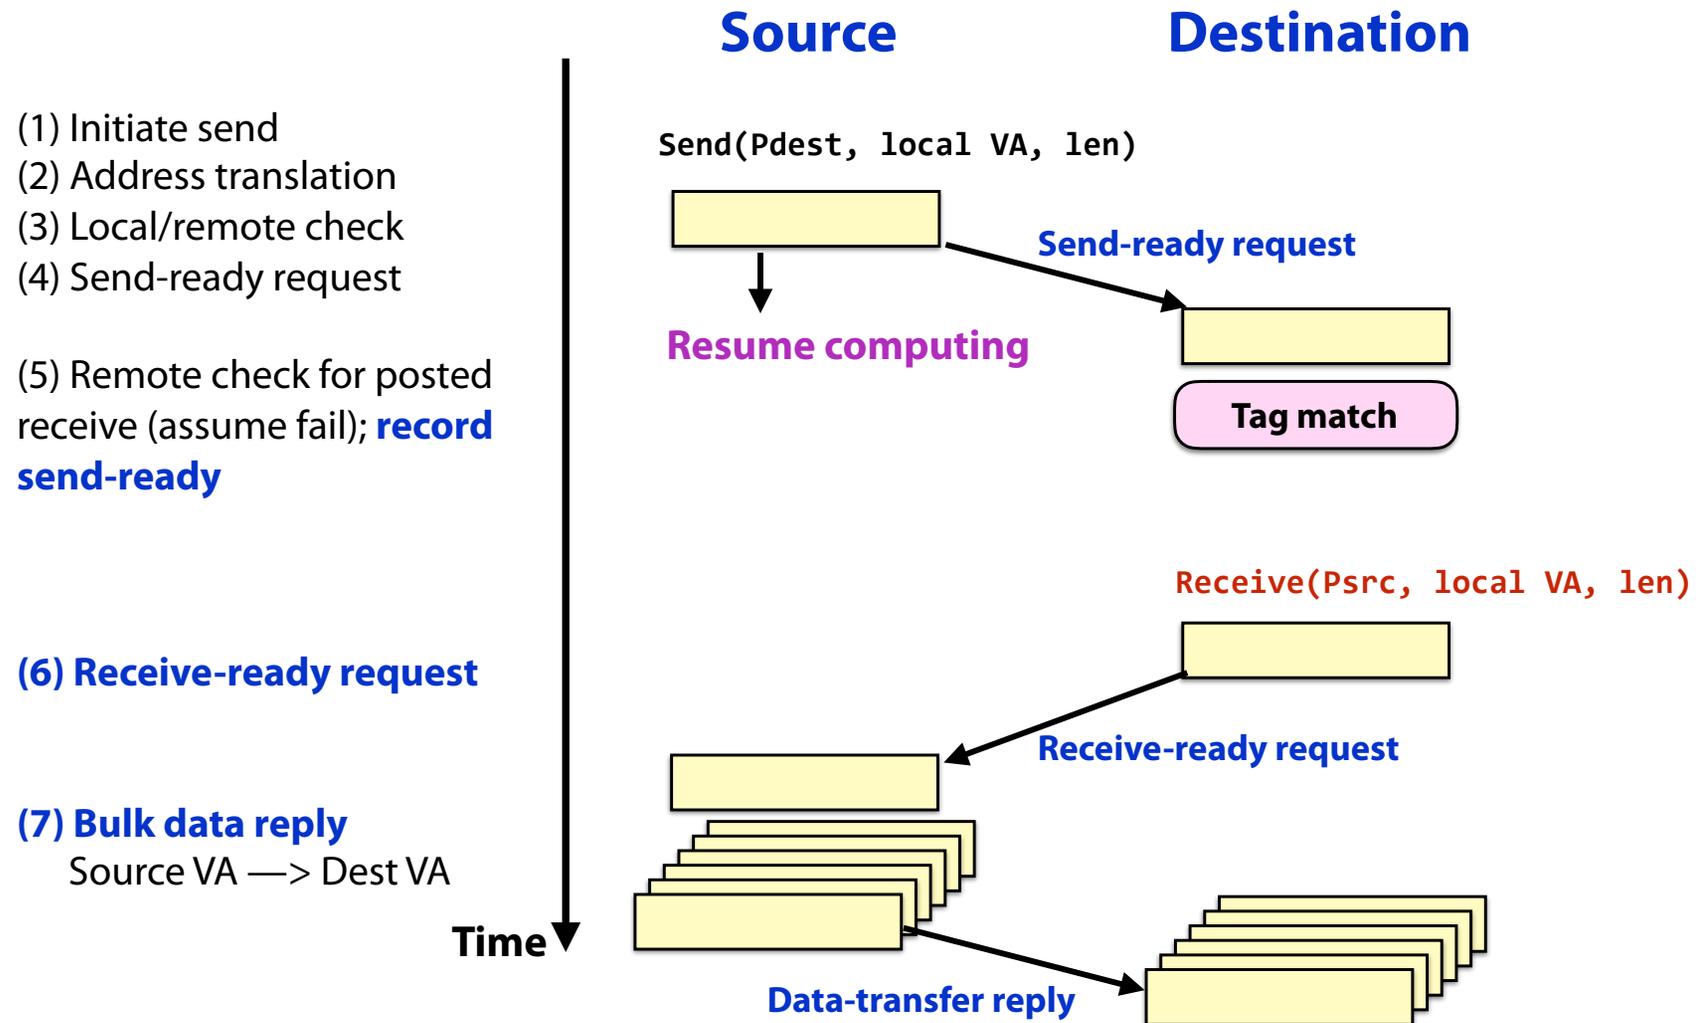

■ Good news:

- source does not stall waiting for the destination to receive

■ Bad news:

- **storage is required within the message layer (?)**

Asynchronous Message Passing: Conservative

- Where is the buffering?
- Contention control? Receiver-initiated protocol?
- What about short messages?

Key Features of Message Passing Abstraction

- **Source knows send address, destination knows receive address**
 - after handshake they both know both
- **Arbitrary storage “outside the local address spaces”**
 - may post many sends before any receives
- **Fundamentally a 3-phase transaction**
 - includes a request / response
 - can use optimistic 1-phase in limited “safe” cases
 - credit scheme

Challenge: Avoiding **Input Buffer Overflow**

- This requires **flow-control on the sources**
- Approaches:
 1. **Reserve space per source (credit)**
 - when is it available for reuse? (utilize ack messages?)
 2. **Refuse input when full**
 - what does this do to the interconnect?
 - backpressure in a reliable network
 - tree saturation? deadlock?
 - what happens to traffic not bound for congested destination?
 3. **Drop packets (?)**
 4. **???**

Challenge: Avoiding Fetch Deadlock

- **Must continue accepting messages**, even when cannot source msgs
 - what if incoming transaction is a request?
 - each may generate a response, which cannot be sent!
 - what happens when internal buffering is full?

Approaches:

1. **Logically independent request/reply networks**
 - physical networks
 - virtual channels with separate input/output queues
2. **Bound requests and reserve input buffer space**
 - $K(P-1)$ requests + K responses per node
 - service discipline to avoid fetch deadlock?
3. **NACK on input buffer full**
 - NACK delivery?

Implementation Challenges: Big Picture

- **One-way transfer** of information
- **No global knowledge**, nor global control
 - barriers, scans, reduce, global-OR give fuzzy global state
- **Very large number of concurrent transactions**
- **Management of input buffer resources**
 - many sources can issue a request and over-commit destination before any see the effect
- **Latency is large enough that you are tempted to “take risks”**
 - e.g., optimistic protocols; large transfers; dynamic allocation

Lecture 27:

Implementing Parallel Runtimes, Part 2

**Parallel Computer Architecture and Programming
CMU 15-418/15-618, Fall 2016**

Objectives

- **What are the costs of using parallelism APIs?**
- **How do the runtimes operate?**

Basis of Lecture

- This lecture is based on runtime and source code analysis of Intel's open source parallel runtimes
 - OpenMP – <https://www.openmp.org/>
 - Cilk – <https://bitbucket.org/intelcilkruntime/intel-cilk-runtime>
- And using the LLVM compiler
 - OpenMP – part of LLVM as of 3.8
 - Cilk - <http://cilkplus.github.io/>

OpenMP and Cilk

- **What do these have in common?**
 - **pthread**
- **What benefit does abstraction versus implementation provide?**

Simple OpenMP Loop Compiled

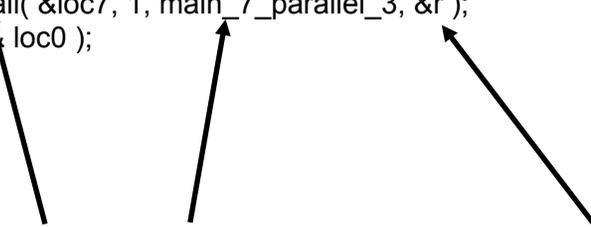

- What is this code doing?
- What do the OpenMP semantics specify?
- How might you accomplish this?

```
extern float foo( void );  
int main (int argc, char** argv) {  
    int i;  
    float r = 0.0;  
    #pragma omp parallel for schedule(dynamic) reduction(+:r)  
    for ( i = 0; i < 10; i ++ ) {  
        r += foo();  
    }  
    return 0;  
}
```

Simple OpenMP Loop Compiled

```
extern float foo( void );
int main (int argc, char** argv) {
    static int zero = 0;
    auto int gtid;
    auto float r = 0.0;
    __kmpc_begin( & loc3, 0 );
    gtid = __kmpc_global_thread_num( & loc3 );
    __kmpc_fork_call( &loc7, 1, main_7_parallel_3, &r );
    __kmpc_end( & loc0 );
    return 0;
}
```

Call a function in parallel with the argument(s)

Simple OpenMP Loop Compiled

- OpenMP “microtask”
 - Each thread runs the task
- Initializes local iteration bounds and reduction
- Each iteration receives a chunk and operates locally
- After finishing all chunks, combine into global reduction

```
struct main_10_reduction_t_5 { float r_10_rpr; };

void main_7_parallel_3( int *gtid, int *btid, float *r_7_shp ) {
    auto int i_7_pr;
    auto int lower, upper, liter, incr;
    auto struct main_10_reduction_t_5 reduce;
    reduce.r_10_rpr = 0.F;
    liter = 0;
    __kmpc_dispatch_init_4( & loc7, *gtid, 35, 0, 9, 1, 1 );
    while ( __kmpc_dispatch_next_4( & loc7, *gtid, &liter,
        &lower, &upper, &incr ) ) {
        for( i_7_pr = lower; upper >= i_7_pr; i_7_pr ++ )
            reduce.r_10_rpr += foo();
    }
    switch( __kmpc_reduce_nowait( & loc10, *gtid, 1, 4,
        &reduce, main_10_reduce_5, &lck ) ) {
    case 1:
        *r_7_shp += reduce.r_10_rpr;
        __kmpc_end_reduce_nowait( & loc10, *gtid, &lck );
    break;
    case 2:
        __kmpc_atomic_float4_add( & loc10, *gtid,
            r_7_shp, reduce.r_10_rpr );
    break;
    default::;
    }
}
```

Simple OpenMP Loop Compiled

■ All code combined

```
extern float foo( void );
int main (int argc, char** argv) {
    static int zero = 0;
    auto int gtid;
    auto float r = 0.0;
    __kmpc_begin( & loc3, 0 );
    gtid = __kmpc_global_thread_num( & loc3 );
    __kmpc_fork_call( &loc7, 1, main_7_parallel_3, &r );
    __kmpc_end( & loc0 );
    return 0;
}

struct main_10_reduction_t_5 { float r_10_rpr; };
static kmp_critical_name lck = { 0 };
static ident_t loc10;

void main_10_reduce_5( struct main_10_reduction_t_5
*reduce_lhs, struct main_10_reduction_t_5 *reduce_rhs )
{
    reduce_lhs->r_10_rpr += reduce_rhs->r_10_rpr;
}
```

```
void main_7_parallel_3( int *gtid, int *btid, float *r_7_shp ) {
    auto int i_7_pr;
    auto int lower, upper, liter, incr;
    auto struct main_10_reduction_t_5 reduce;
    reduce.r_10_rpr = 0.F;
    liter = 0;
    __kmpc_dispatch_init_4( & loc7,*gtid, 35, 0, 9, 1, 1 );
    while ( __kmpc_dispatch_next_4( & loc7, *gtid, &liter,
    &lower, &upper, &incr ) ) {
        for( i_7_pr = lower; upper >= i_7_pr; i_7_pr ++ )
            reduce.r_10_rpr += foo();
    }
    switch( __kmpc_reduce_nowait( & loc10, *gtid, 1, 4,
    &reduce, main_10_reduce_5, &lck ) ) {
    case 1:
        *r_7_shp += reduce.r_10_rpr;
        __kmpc_end_reduce_nowait( & loc10, *gtid, &lck);
    break;
    case 2:
        __kmpc_atomic_float4_add( & loc10, *gtid, r_7_shp,
        reduce.r_10_rpr );
    break;
    default::;
    }
}
```

Fork Call

- **“Forks” execution and calls a specified routine (microtask)**
- **Determine how many threads to allocate to the parallel region**
- **Setup task structures**
- **Release allocated threads from their idle loop**

Iteration Mechanisms

- **Static, compile time iterations**
 - `__kmp_for_static_init`
 - **Compute one set of iteration bounds**

- **Everything else**
 - `__kmp_dispatch_next`
 - **Compute the next set of iteration bounds**

OMP Barriers

- **Two phase -> gather and release**
 - **Gather non-master threads pass, master waits**
 - **Release is opposite**

- **Barrier can be:**
 - **Linear**
 - **Tree**
 - **Hypercube**
 - **Hierarchical**

OMP Atomic

- Can the compiler do this in a read-modify-write (RMW) op?
- Otherwise, create a compare-and-swap loop

```
T* val;  
T update;  
#pragma omp atomic  
    *val += update;
```

If T is int, this is “lock add ...”.

If T is float, this is “lock cmpxchg ...”

Why?

OMP Tasks

- **#pragma omp task depend (inout:x) ...**
- **Create microtasks for each task**
 - **Track dependencies by a list of address / length tuples**

Cilk

- Covered in Lecture 5
- We discussed the what and why, now the how

Simple Cilk Program Compiled

- **What is this code doing?**
- **What do the Cilk semantics specify?**
- **Which is the child? Which is the continuation?**

```
int fib(int n) {  
    if (n < 2)  
        return n;  
    int a = cilk_spawn fib(n-1);  
    int b = fib(n-2);  
    cilk_sync;  
    return a + b;  
}
```

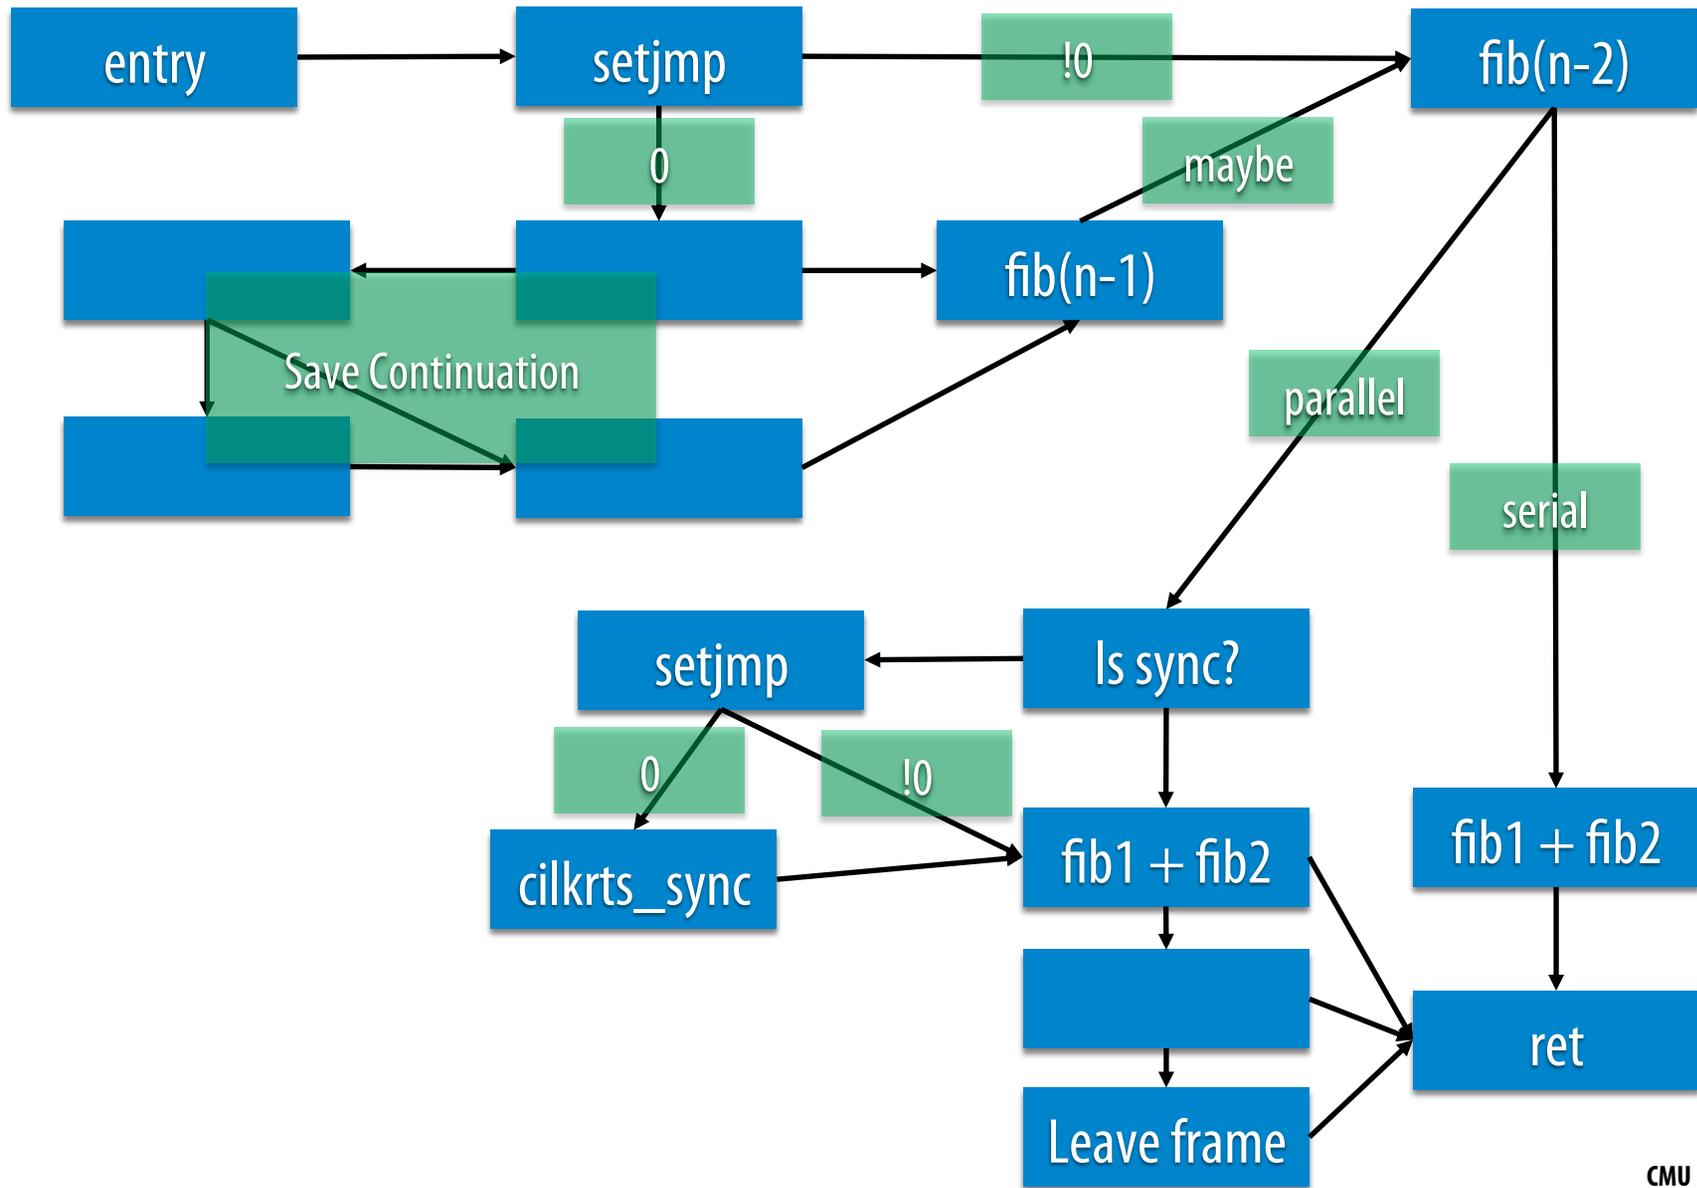

How to create a continuation?

- Continuation needs all of the state to continue
 - Register values, stack, etc.
- What function allows code to jump to a prior point of execution?
- `Setjmp(jmp_buf env)`
 - Save stack context
 - Return via `longjmp(env, val)`
 - `Setjmp` returns 0 if saving, val if returning via `longjmp`

Basic Block

- **Unit of Code Analysis** 
- **Sequence of instructions**
 - **Execution can only enter at the first instruction**
 - **Cannot jump into the middle**
 - **Execution can only exit at the last instruction**
 - **Branch or Function Call**
 - **Or the start of another basic block (fall through)**

Simple Cilk Program Revisited

Cilk Workers

- **While there may be work**
 - **Try to get the next item from our queue**
 - **Else try to get work from a random queue**
 - **If there is no work found, wait on semaphore**

- **If work item is found**
 - **Resume with the continuation's stack**

Thread Local Storage

- **Linux supports thread local storage**
 - **New: C11 - `_Thread_local` keyword**
 - **one global instance of the variable per thread**
 - **Compiler places values into `.tbss`**
 - **OS provides each thread with this space**

- **Since Cilk and OpenMP are using pthreads**
 - **These values are in the layer below them**
