Jonathan Ragan-Kelley (MIT)

Tunes

Celia Cruz

La Vida es un Carnival

"It was after a trip to Pittsburgh where we really decided this salsa thing was going to go big."

- Úrsula

Course themes:

Designing computer systems that <u>scale</u>

(running faster given more resources)

Designing computer systems that are efficient

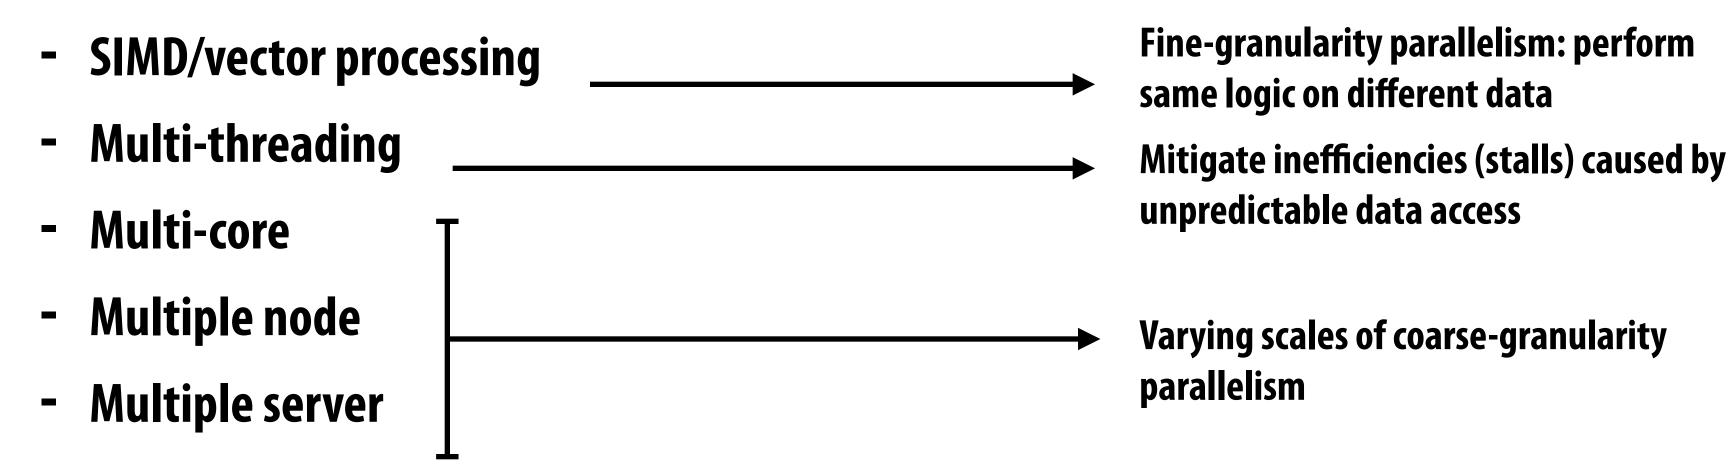

(running faster under constraints on resources)

Techniques discussed:

Exploiting parallelism in applications Exploiting locality in applications Leveraging HW specialization

Hardware trend: specialization of execution

Multiple forms of parallelism

Heterogeneous execution capability

- Programmable, latency-centric (e.g., "CPU-like" cores)
- Programmable, throughput-optimized (e.g., "GPU-like" cores)
- Fixed-function, application-specific (e.g., image/video/audio processing)

Motivation for parallelism and specialization: maximize compute capability given constraints on chip area, power.

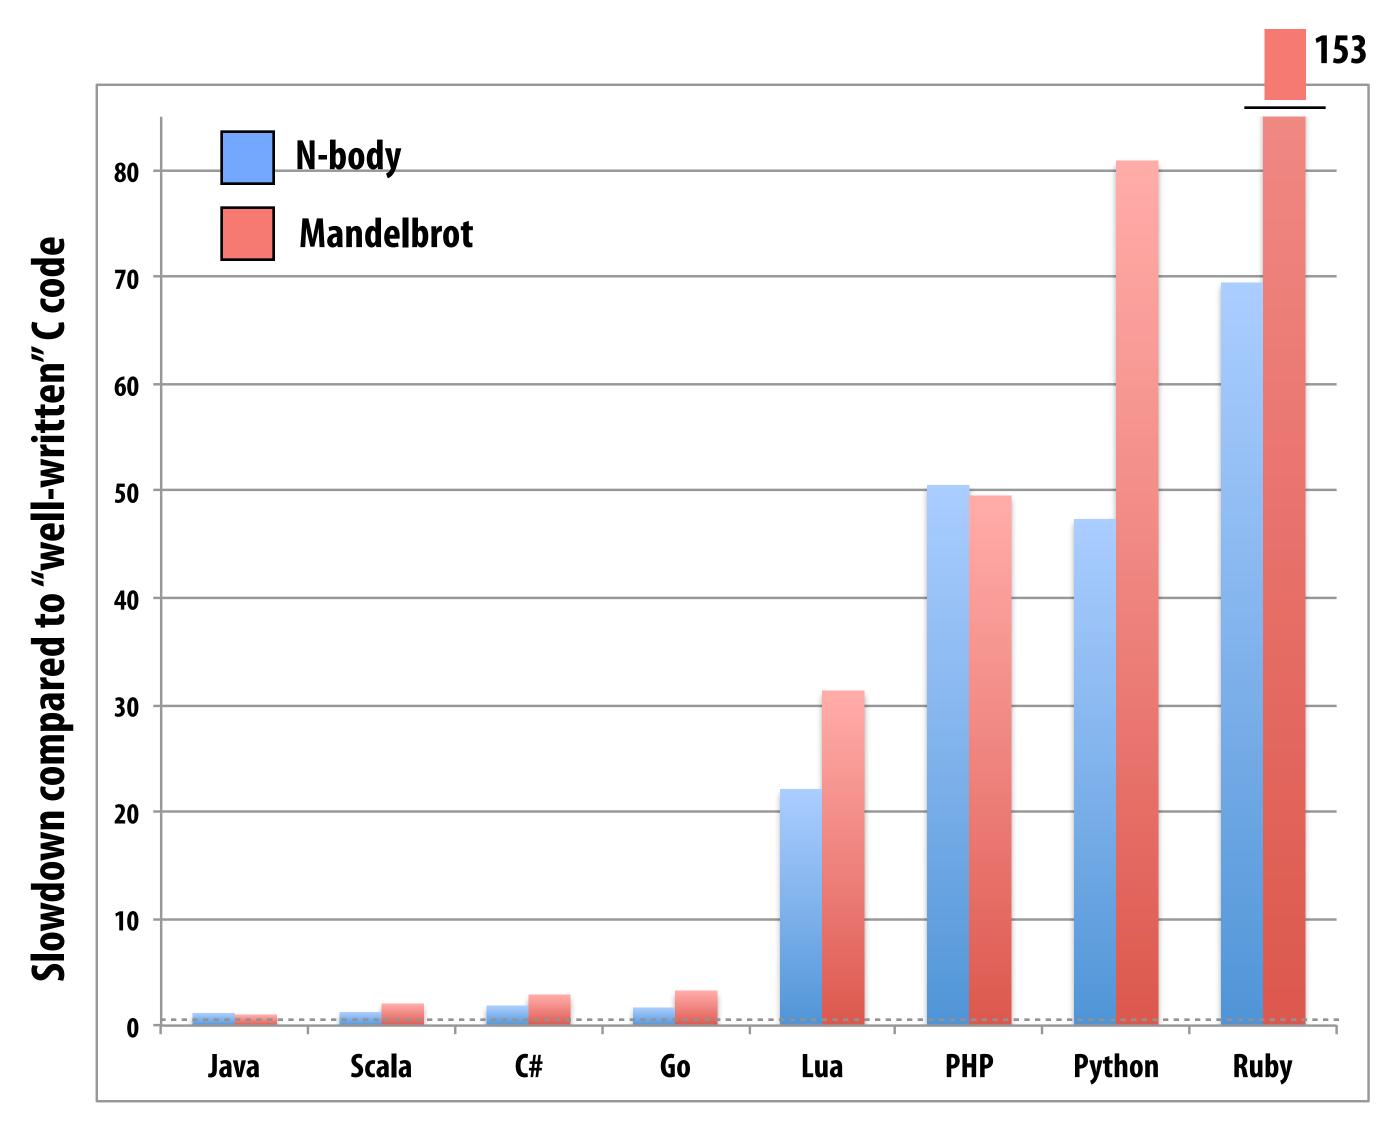

Result: amazingly high compute capability in a wide range of devices!

Claim: most software uses modern hardware resources inefficiently

- Consider a piece of sequential C code
 - Let's consider the performance of this baseline performance)
- Well-written sequential C code: ~ 5-10x faster
- Assembly language program: another small constant factor faster
- Java, Python, PHP, etc. ??

Credit: Pat Hanrahan

Code performance relative to C (single core)

Source: The Computer Language Benchmarks Game: http://shootout.alioth.debian.org

Even good C code is inefficient

Recall Assignment 1's Mandelbrot program

For execution on this laptop: quad-core, Intel Core i7, AVX instructions...

Single core, with AVX vector instructions: 5.8x speedup over C implementation Multi-core + hyper-threading + AVX instructions: 21.7x speedup

Conclusion: basic C implementation leaves a lot of performance on the table

Making efficient use of modern machines is challenging

(proof by assignments 2, 3, and 4)

In our assignments you only programmed homogeneous parallel computers.

And parallelism in that context was not easy.

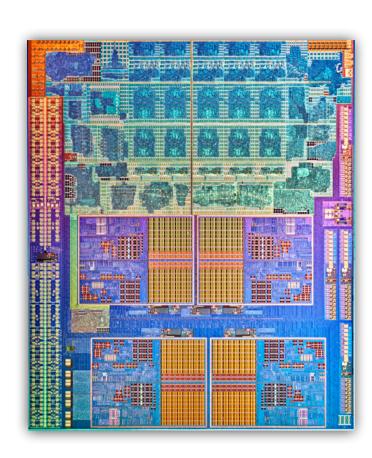

Assignment 2: GPU cores only

Assignment 3: Blacklight (multiple CPUs with relatively fast interconnect)

Assignment 4: multiple parallel machines

Power-efficient heterogeneous platforms

Integrated CPU + GPU

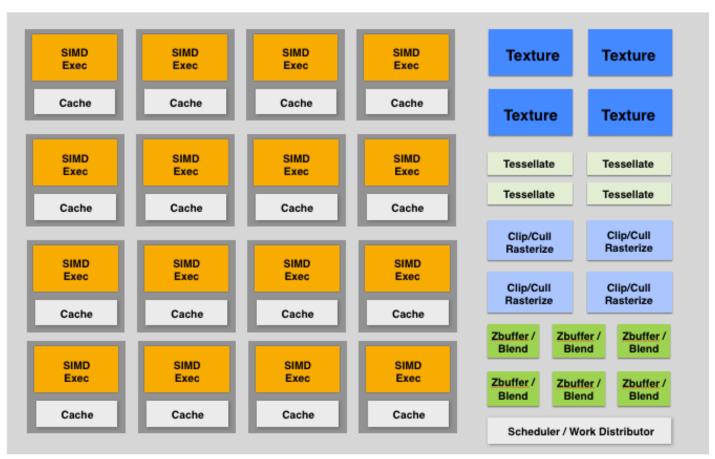

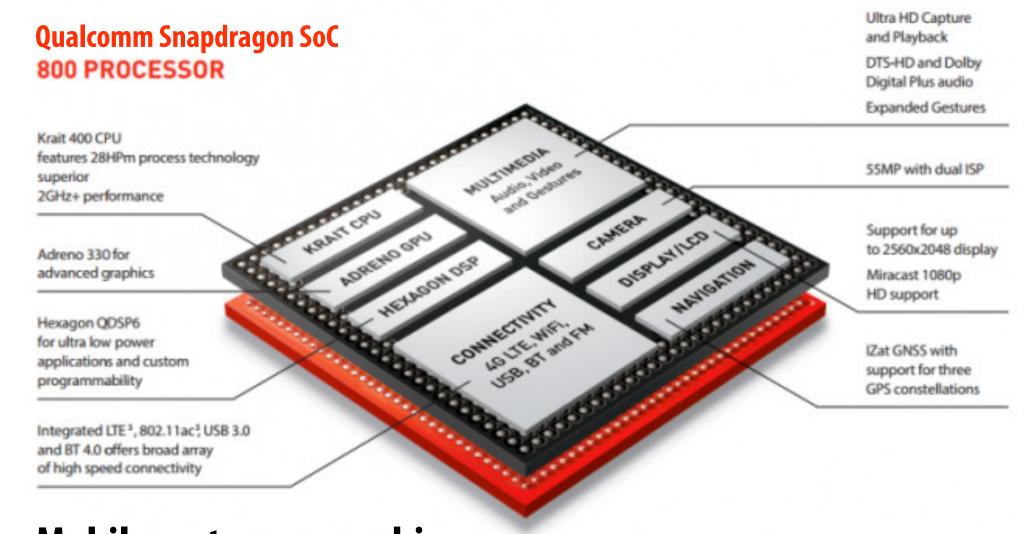

CPU+data-parallel accelerator

GPU:

throughput cores + fixed-function

Mobile system-on-a-chip: CPU+GPU+media processing

Hardware diversity is a huge challenge

- Machines with very different performance characteristics
- Even worse: different technologies and performance characteristics within the same machine at different scales
 - Within a core: SIMD, multi-threading: fine-granularity sync and communication
 - Across cores: coherent shared memory via fast on-chip network
 - Hybrid CPU+GPU multi-core: incoherent (potentially) shared memory
 - Across racks: distributed memory, multi-stage network

Variety of programming models to abstract HW

- Machines with very different performance characteristics
- Worse: different technologies and performance characteristics within the same machine at different scales
 - Within a core: SIMD, multi-threading: fine grained sync and comm.
 - Abstractions: SPMD programming (ISPC, Cuda, OpenCL)
 - Across cores: coherent shared memory via fast on-chip network
 - Abstractions: OpenMP shared address space, Cilk, TBB
 - Hybrid CPU+GPU multi-core: incoherent (potentially) shared memory
 - Abstractions: OpenCL
 - Across racks: distributed memory, multi-stage network
 - Abstractions: message passing (MPI, Go channels, Charm++)

Credit: Pat Hanrahan

Huge challenge

- Machines with very different performance characteristics
- Worse: different performance characteristics within <u>the same</u> <u>machine</u> at different scales
- To be efficient, software must be optimized for HW characteristics
 - Difficult even in the case of one level of one machine **
 - Combinatorial complexity of optimizations when considering a complex machine, or different machines
 - Loss of software portability

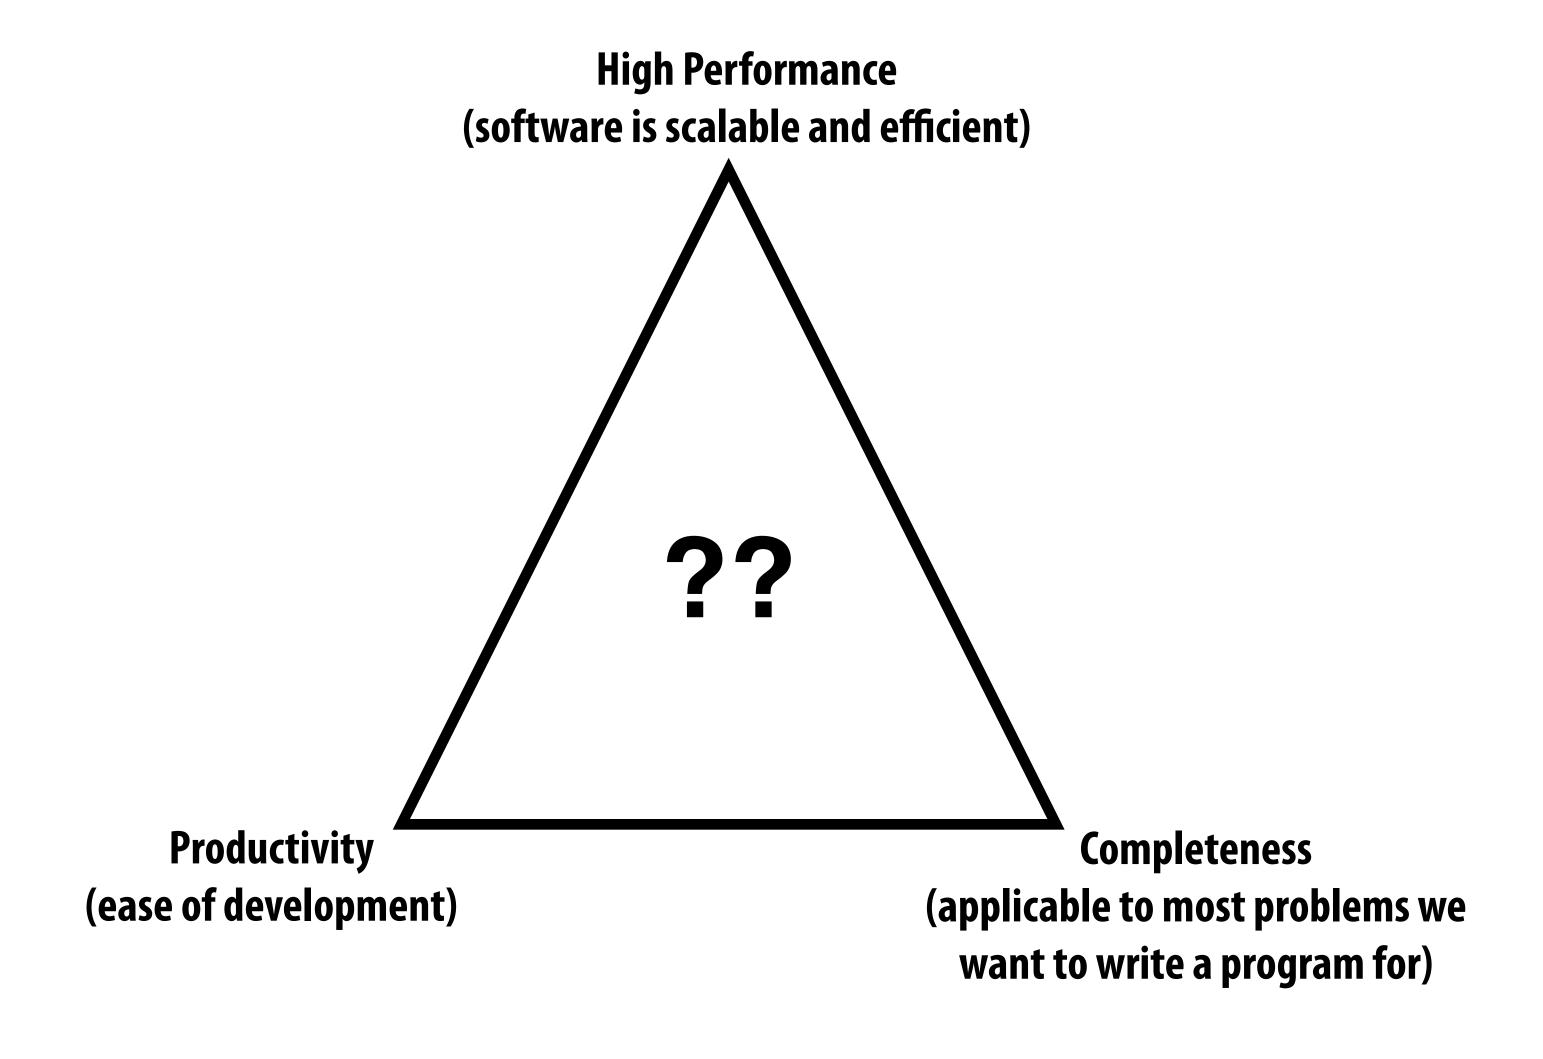

** Little success developing automatic tools to identify efficient HW mapping for arbitrary, complex applications

Credit: Pat Hanrahan

Open computer science question:

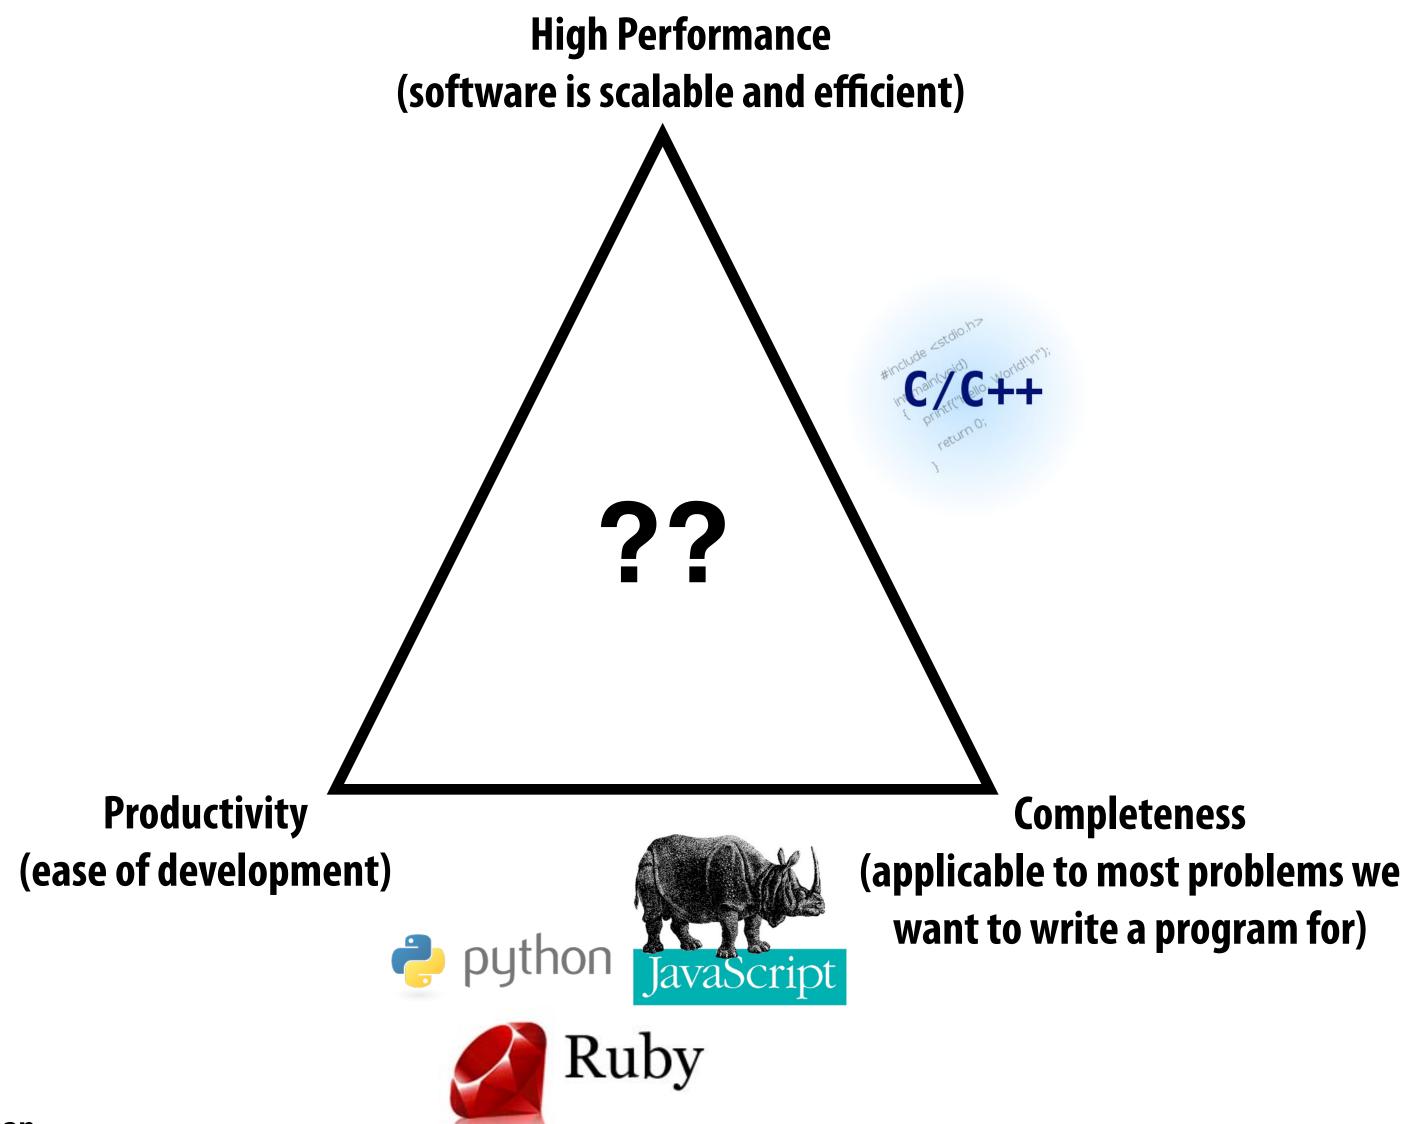

How do we enable programmers to write software that efficiently uses these parallel machines?

The [magical] ideal parallel programming language

Successful programming languages

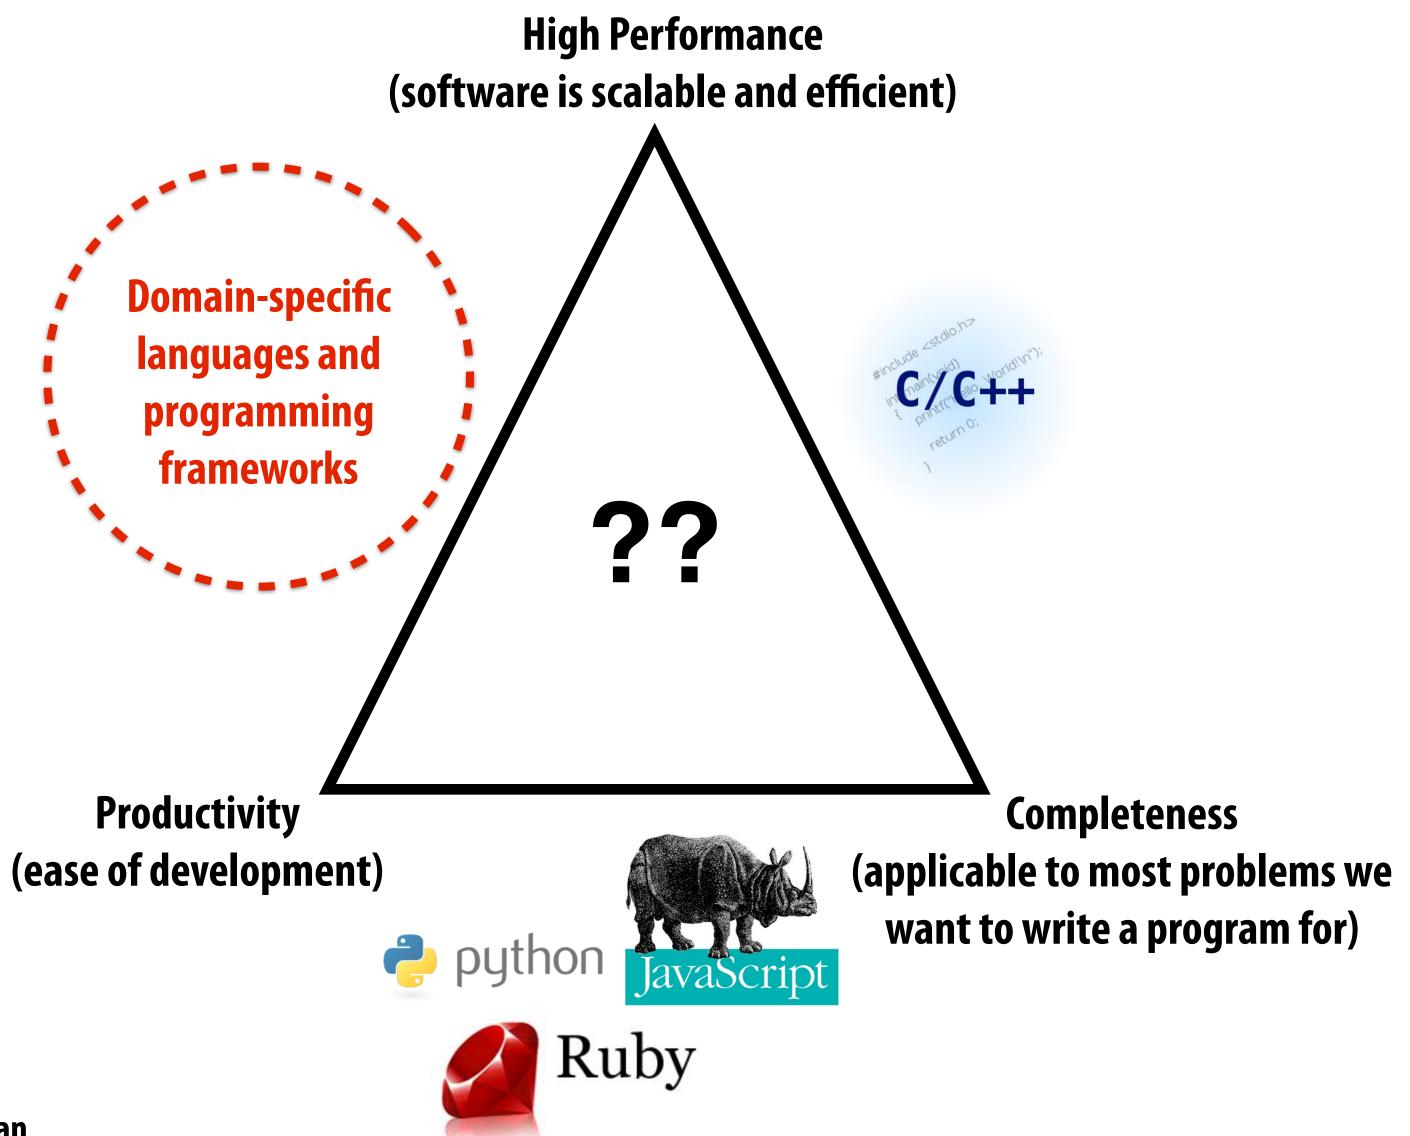

Here: definition of success = widely used

Credit: Pat Hanrahan

Growing interest in domain-specific programming systems

To realize high performance and productivity: willing to sacrifice completeness

Credit: Pat Hanrahan

Domain-specific programming systems

- Main idea: raise level of abstraction
- Introduce high-level programming primitives specific to an application domain
 - Productive: intuitive to use, portable across machines, primitives correspond to behaviors frequently used to solve problems in targeted domain
 - Performant: system uses domain knowledge to provide efficient, optimized implementation(s)
 - Given a machine: system knows what algorithms to use, parallelization strategies to employ for this domain
 - Optimization goes beyond efficient mapping of software to hardware! The hardware platform itself can be optimized to the abstractions as well
- Cost: loss of generality/completeness

Two domain-specific programming examples

1. Liszt: scientific computing

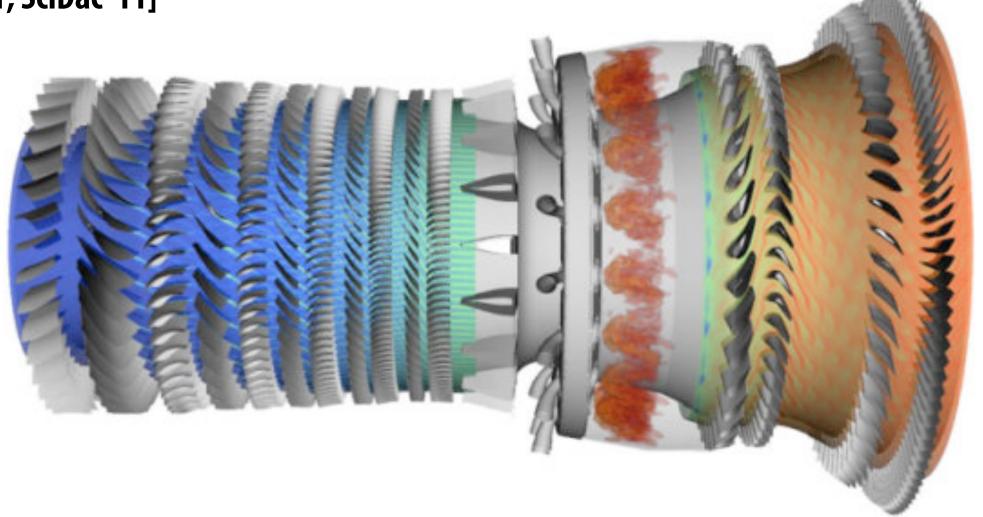

2. Halide: image processing

(Bonus slides contain a third example: OpenGL)

Example 1:

Lizst: a language for solving PDE's on meshes

[DeVito et al. Supercomputing 11, SciDac'11]

Fields on unstructured meshes

Coloring key:

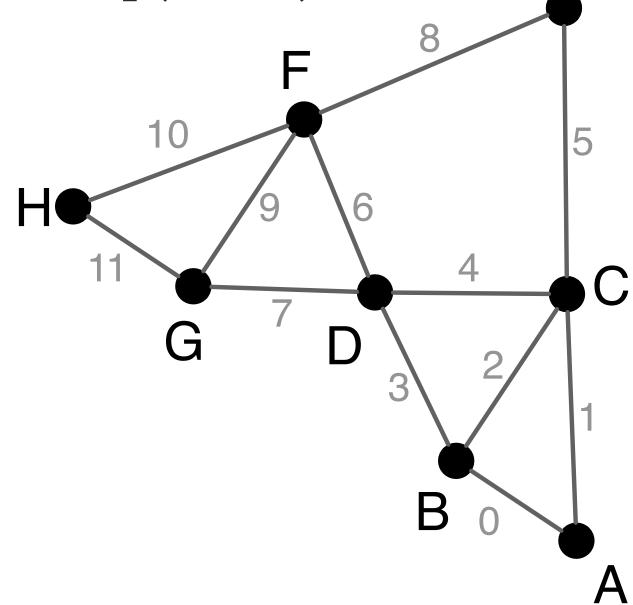

Fields
Mesh entity

```
val Position = FieldWithLabel[Vertex,Float3]("position")
```

```
val Temperature = FieldWithConst[Vertex,Float](0.0f)
val Flux = FieldWithConst[Vertex,Float](0.0f)
val JacobiStep = FieldWithConst[Vertex,Float](0.0f)
```

Notes:

Fields are a higher-kinded type (special function that maps a type to a new type)

Explicit algorithm: heat conduction on grid

```
Coloring key:
var i = 0;
                                                Fields
while ( i < 1000 ) {
                                                Mesh
  Flux(vertices(mesh)) = 0.f;
                                                Topology functions
  JacobiStep(vertices(mesh)) = 0.f;
                                                Iteration over set
  for (e <- edges(mesh)) {</pre>
    val v1 = head(e)
    val v2 = tail(e)
    val dP = Position(v1) - Position(v2)
    val dT = Temperature(v1) - Temperature(v2)
    val step = 1.0f/(length(dP))
    Flux(v1) += dT*step
    Flux(v2) -= dT*step
                                                 10
    JacobiStep(v1) += step
    JacobiStep(v2) += step
```

Liszt's topological operators

```

Liszt programming

- Liszt program describes operations on fields of an abstract mesh representation
- Application specifies type of mesh (regular, irregular) and its topology
- Mesh representation is chosen by Liszt (not by the programmer)
 - Based on mesh type, program behavior, and machine

Compiling to parallel computers

Recall challenges you have faced in your assignments

- 1. Identify parallelism
- 2. Identify data locality
- 3. Reason about required synchronization

Key: determining program dependencies

1. Identify parallelism

- Absence of dependencies implies code can be executed in parallel

2. Identify data locality

 Partition data based on dependencies (localize dependent computations for faster synchronization)

3. Reason about required synchronization

- Synchronization is needed to respect existing dependencies (must wait until the values a computation depends on are known)

In general programs, compilers are unable to infer dependencies at global scale: a[i] = b[f(i)] (must execute f(i) to know dependency)

Liszt is constrained to allow dependency analysis

"stencil" = mesh elements accessed in an iteration of loop Inferring "stencils": = dependencies for the iteration

Statically analyze code to find stencil of each top-level for loop

- **Extract nested mesh element reads**
- Extract field operations

```
Edge 6's read stencil is F and D
for (e <- edges(mesh)) {</pre>
  val v1 = head(e)
  val v2 = tail(e)
  val dP = Position(v1) - Position(v2)
  val dT = Temperature(v1) - Temperature(v2)
  val step = 1.0f/(length(dP))
   Flux(v1) += dT*step
                                                           e in
                                                                        vertices(mesh)
                                                       edges(mesh)
   Flux(v2) -= dT*step
                                                                       Read/Write Flux
   JacobiStep(v1) += step
                                                                       Read/Write JacobiStep
                                                                       Write Temperature
   JacobiStep(v2) += step
                                                                   tail(e)
                                                  head(e)
                                                                Read Position, Temperature
                                               Read Position, Temperature
•••
                                               Write Flux, JacobiStep
                                                                 Write Flux, JacobiStep
```

Restrict language for dependency analysis

"Language Restrictions"

– Mesh elements only accessed through built-in topological functions:

```
cells(mesh), ...
```

Single static assignment:

```
val v1 = head(e)
```

– Data in fields can only be accessed using mesh elements:

No recursive functions

Allows compiler to automatically infer stencil

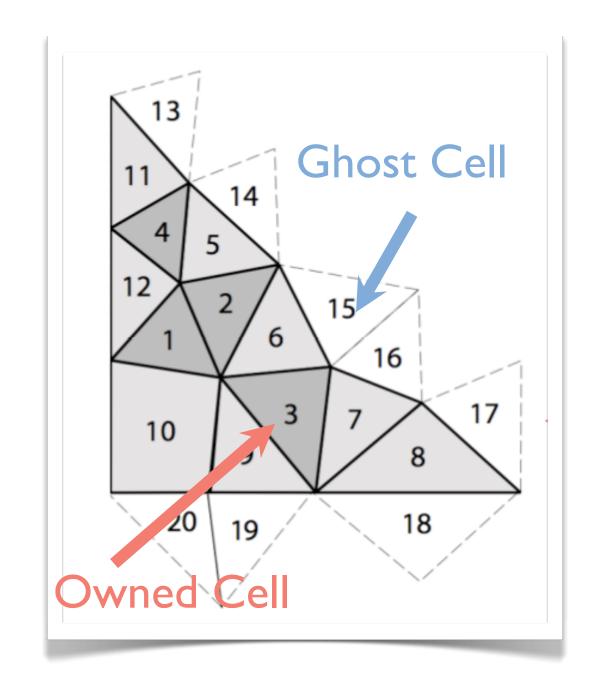

Portable parallelism: use dependencies to implement different parallel execution strategies

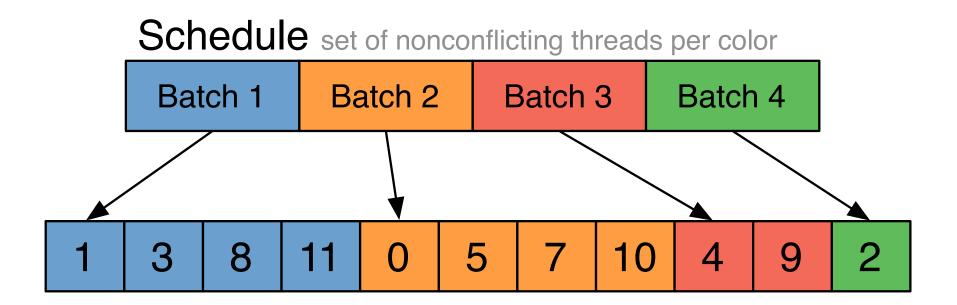

Partitioning

- Assign partition to each computational unit
- Use ghost elements to coordinate cross-boundary communication.

Coloring

- Calculate interference between work items on domain
- Schedule work-items into non-interfering batches

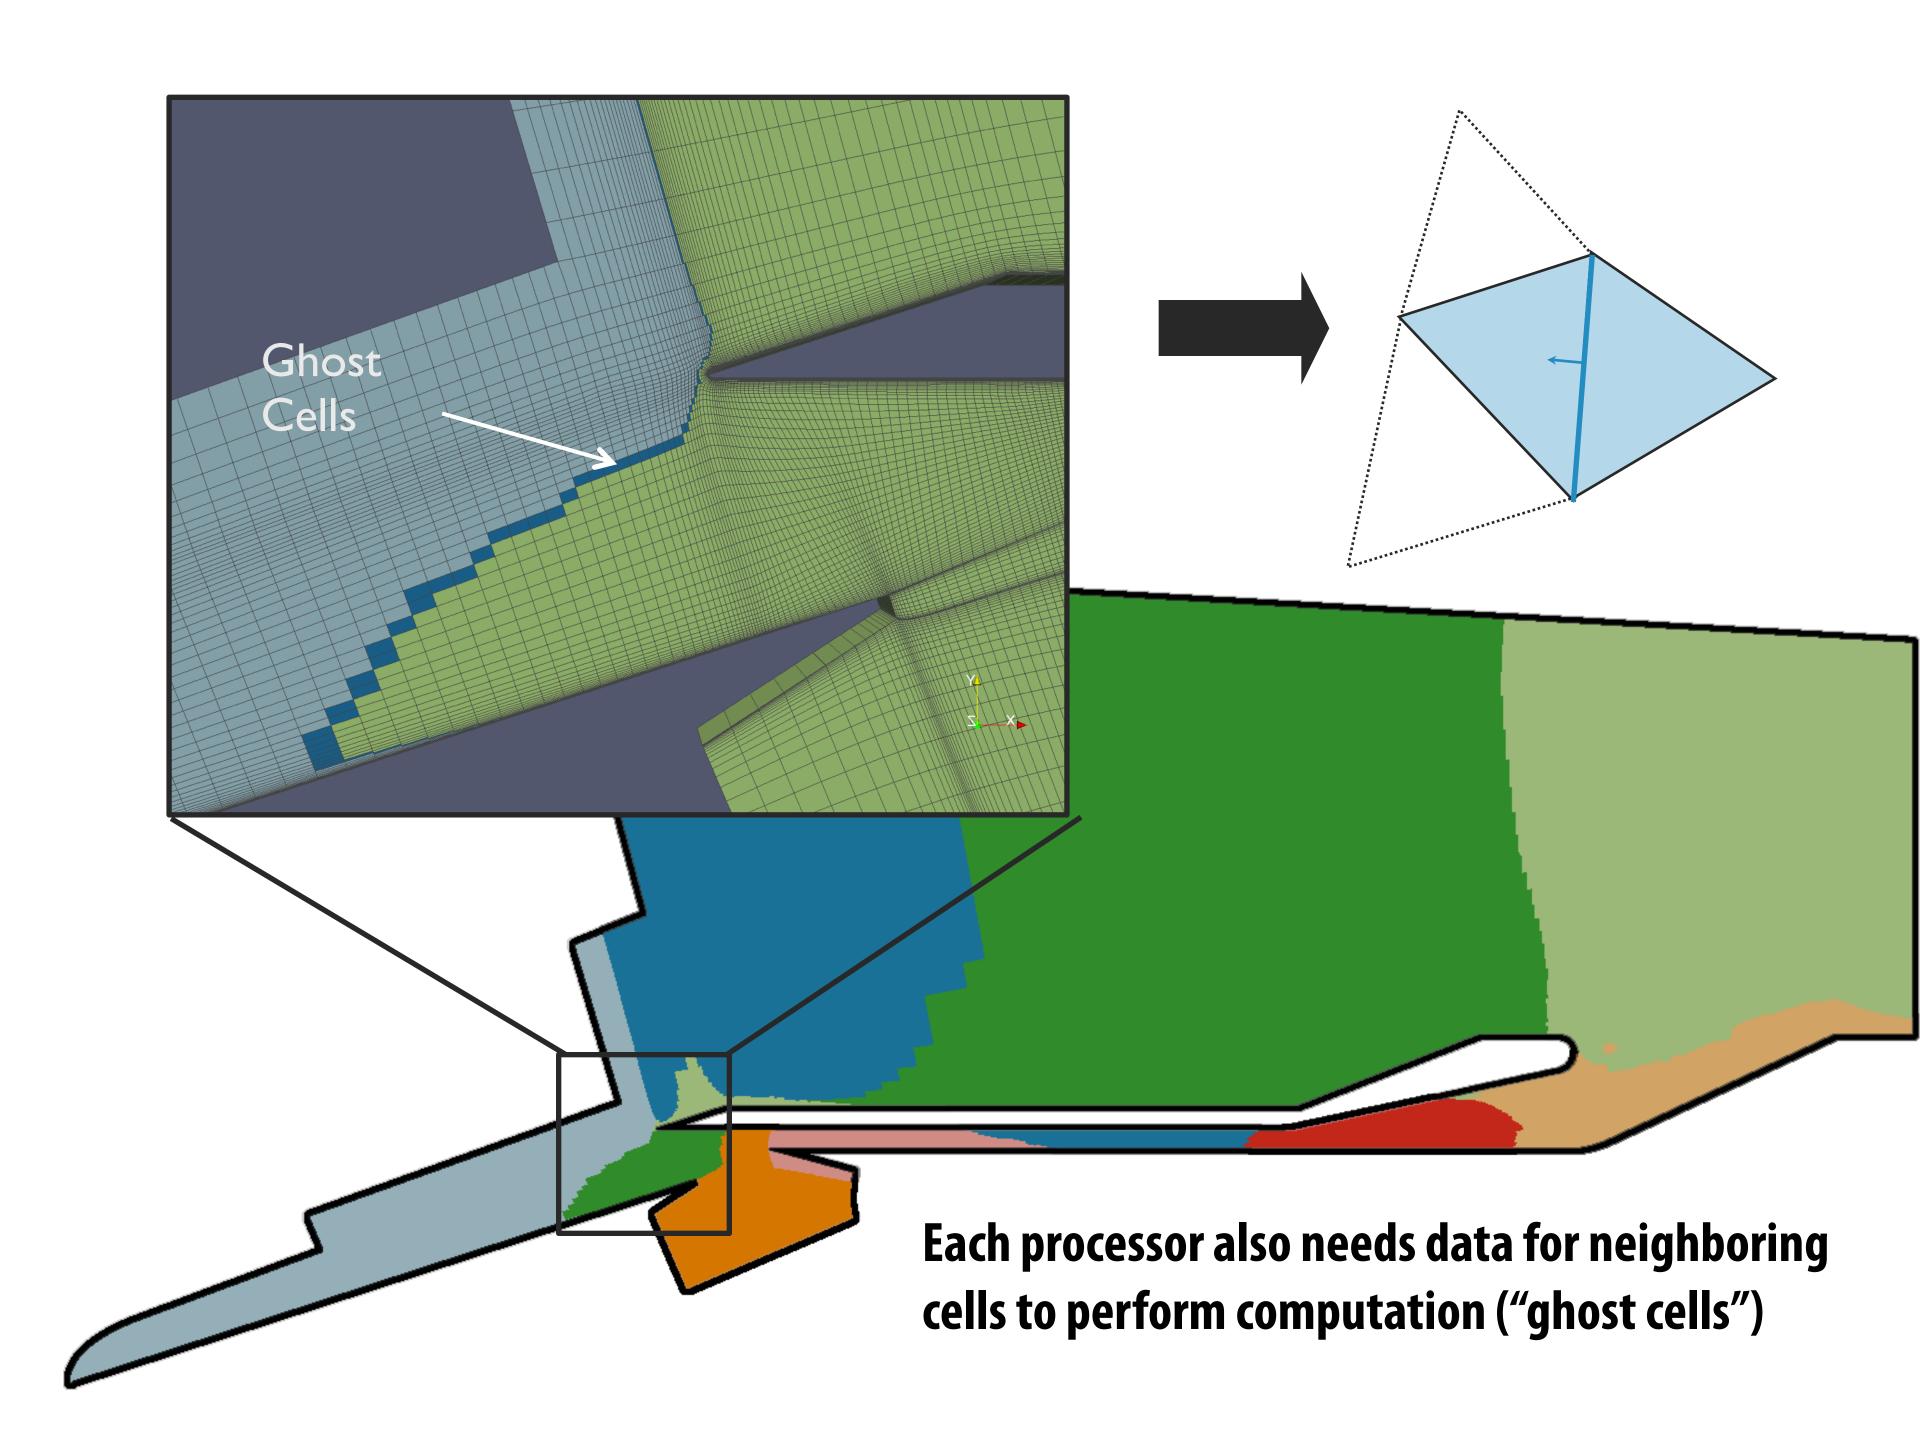

Distribution memory implementation of Liszt Mesh + Stencil -> Graph -> Partition

```
for(f <- faces(mesh)) {</pre>
  rhoOutside(f) :=
    calc_flux( f,rho(outside(f) ))
    + calc_flux( f,rho(inside(f) ))
     Initial Partition
     (by ParMETIS)
                                     Consider distributed memory implementation
```

Store region of mesh on each node in a cluster

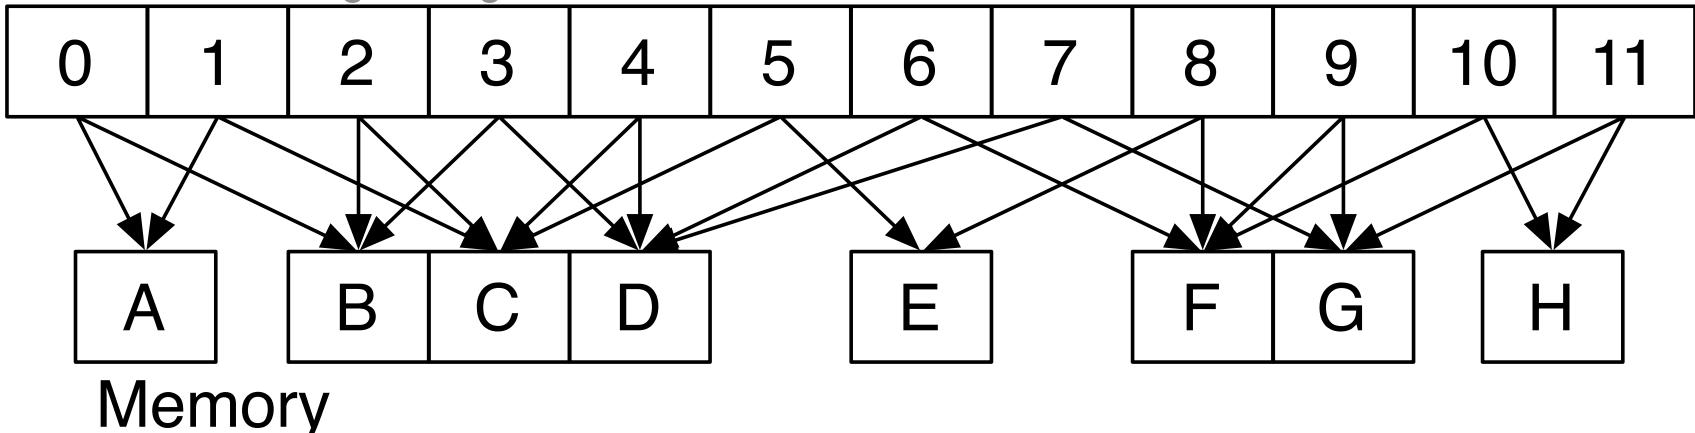

(ParMETIS is a tool to partition meshes)

GPU implementation: parallel reductions

Previous example, one region of mesh per processor (or node in MPI cluster) On GPU, natural parallelization is one edge per CUDA thread

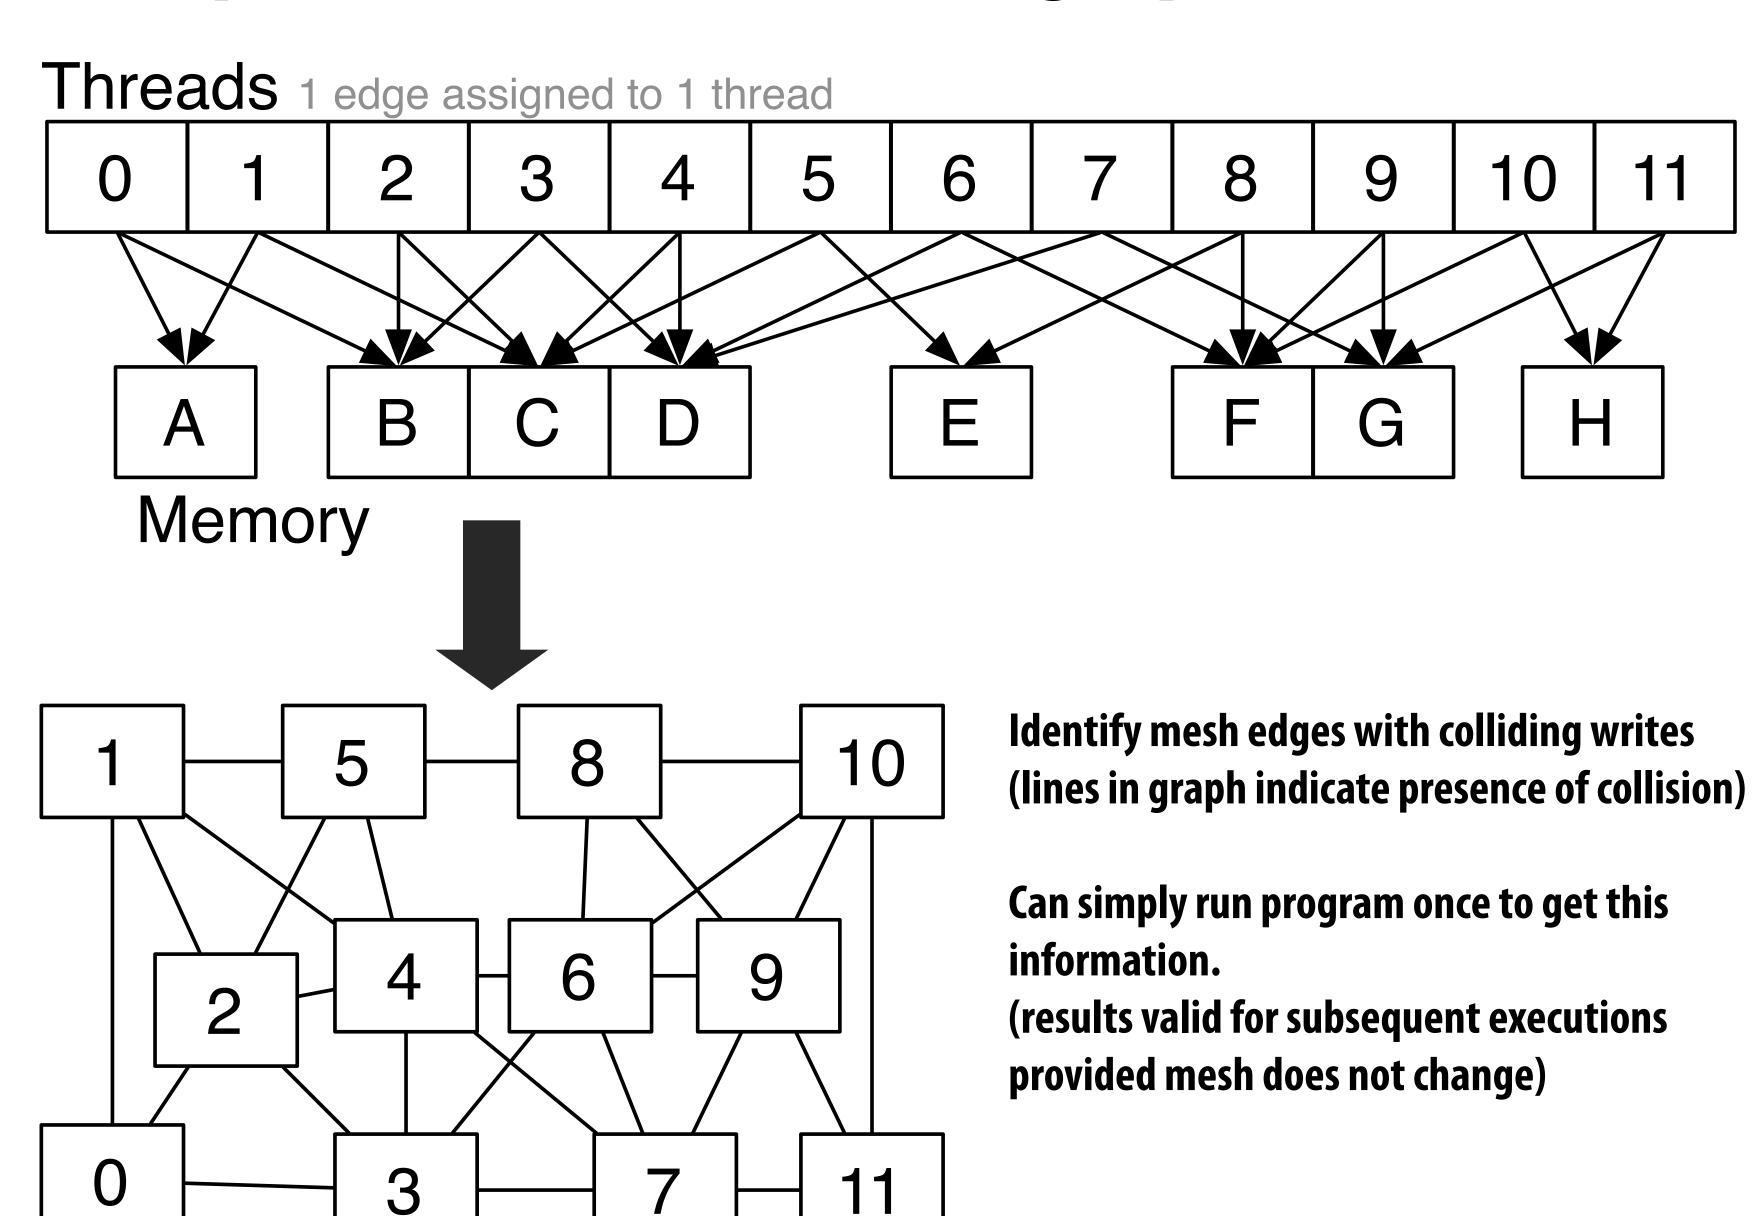

```
for (e <- edges(mesh)) {
    ...
Flux(v1) += dT*step
Flux(v2) -= dT*step
...
}</pre>
```

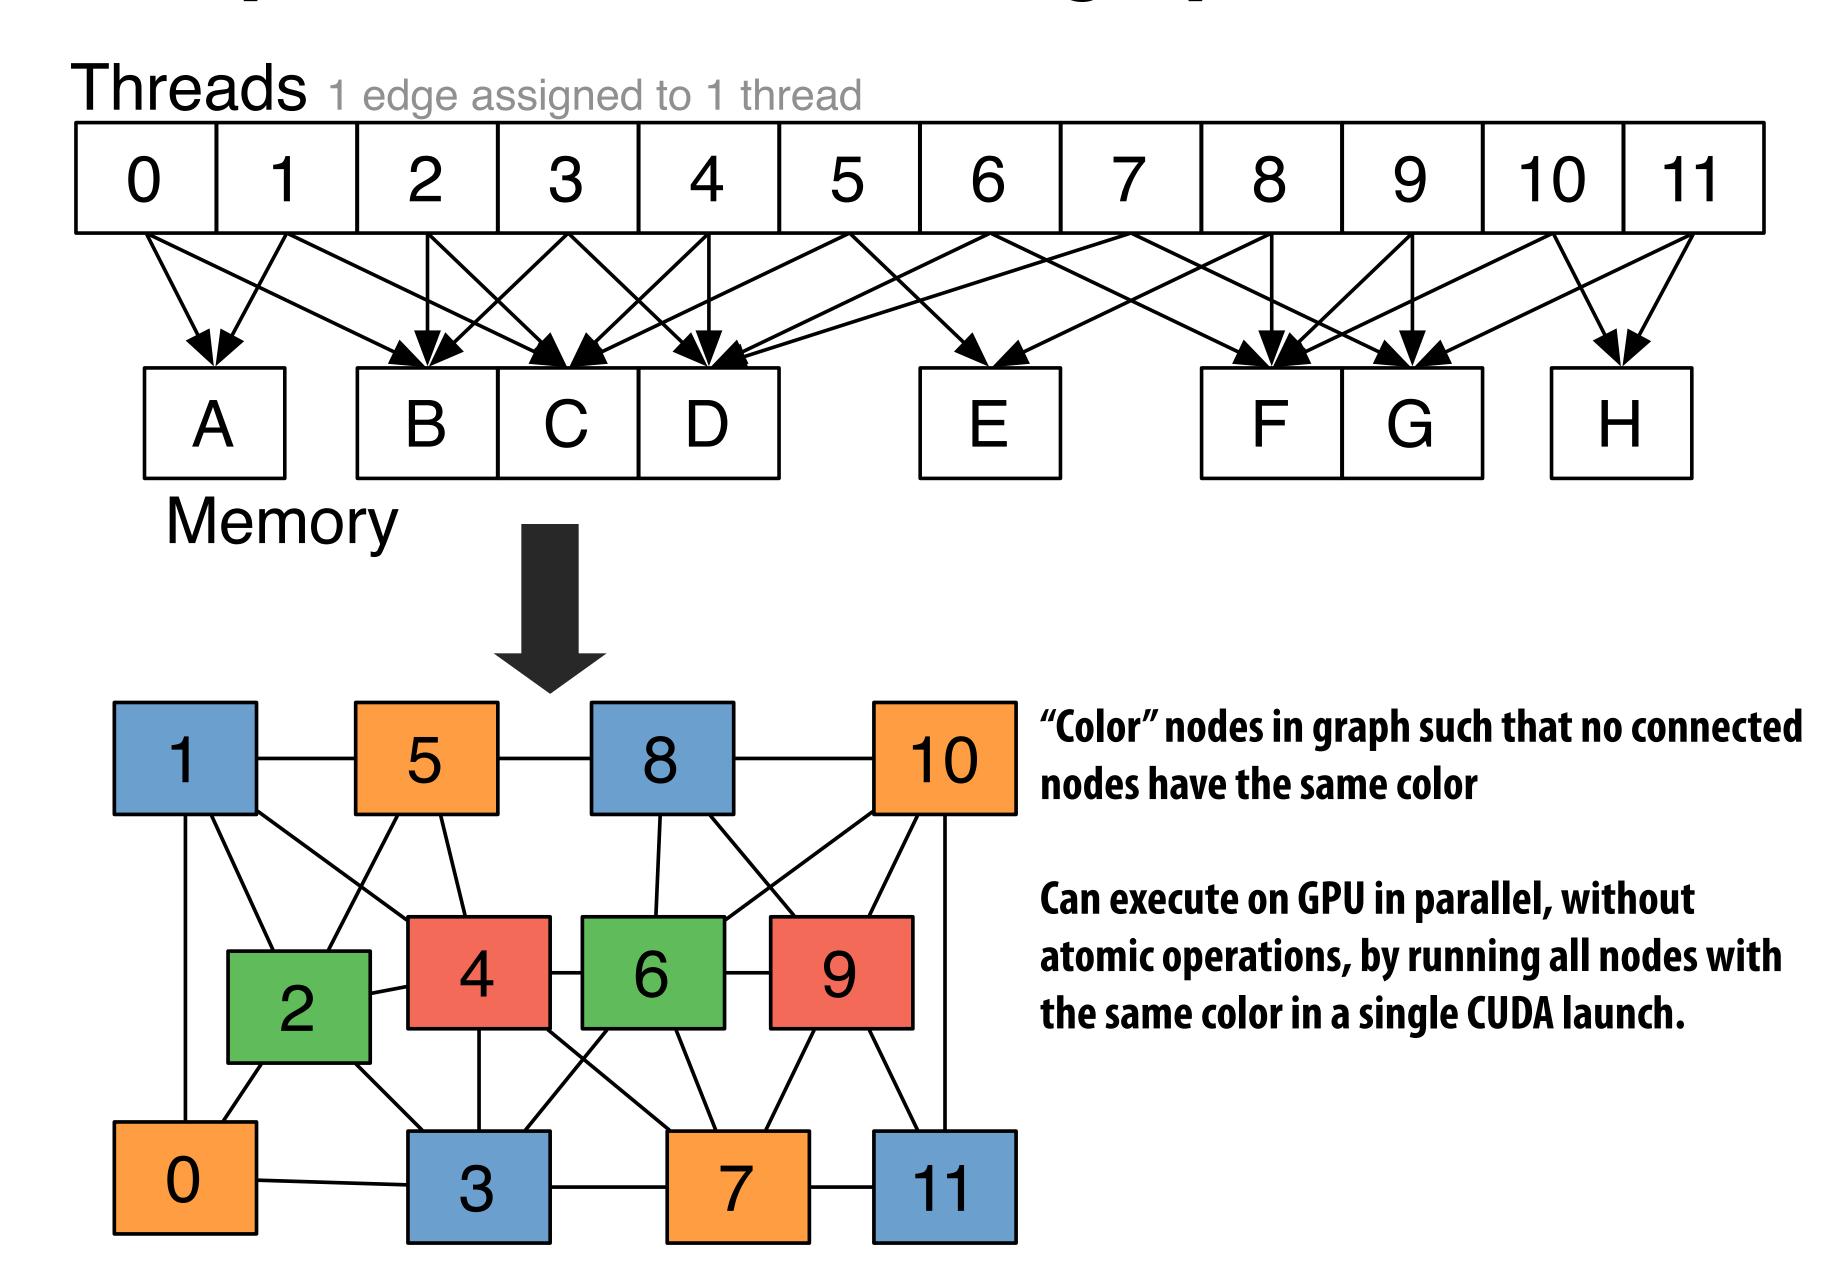

Different edges share a vertex: requires atomic update of per-vertex field data

GPU implementation: conflict graph

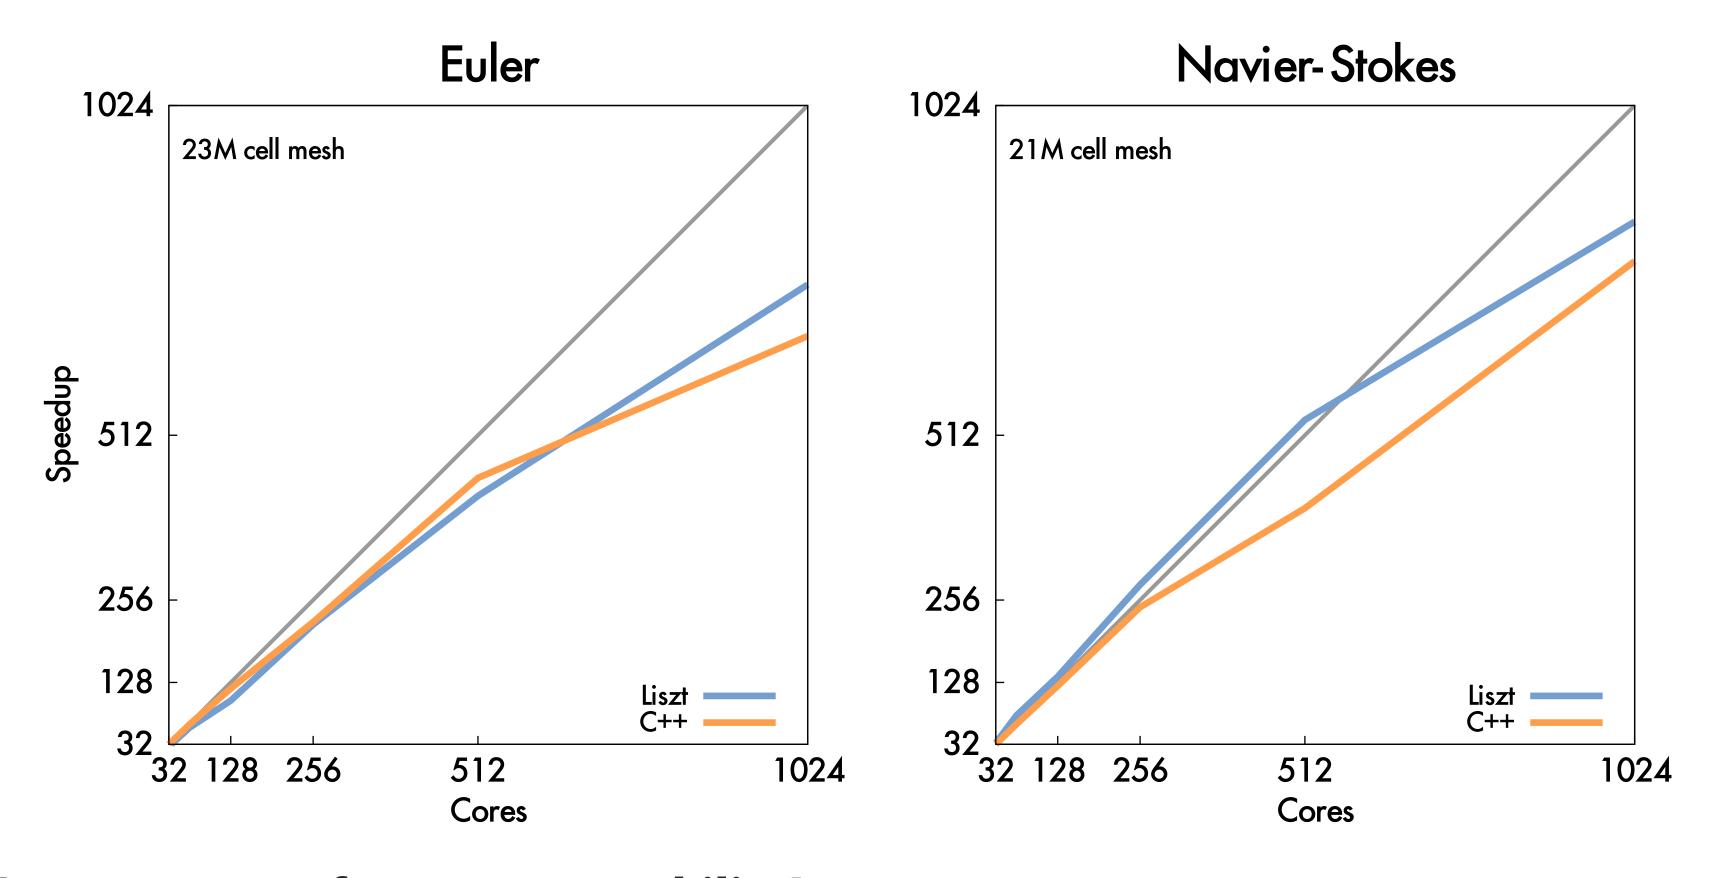

GPU implementation: conflict graph

MPI performance of Lizst program

256 nodes, 8 cores per node

Important: performance portability!
Same Liszt program also runs with high efficiency on GPU (results not shown here).
But uses a <u>different algorithm!</u> (graph coloring)

Liszt summary

Productivity:

- Abstract representation of mesh: vertices, edges, faces, fields
- Intuitive topological operators

Portability

- Same code runs on cluster of CPUs (MPI runtime) and GPUs

High-Performance

- Language constrained to allow compiler to track dependencies
- Used for locality-aware partitioning in distributed memory implementation
- Used for graph coloring in GPU implementation
- Completely different parallelization strategies for different platforms
- Underlying mesh representation can be customized by system based on usage and platform (e.g, struct of arrays vs. array of structs)

Example 2:

Halide: a domain-specific language for image processing

Slide acknowledgments: Jonathan Ragan-Kelley (MIT)

What does this C++ code do?

Total work ~ 6 x width() x height()

```
void blur(const Image &in, Image &blurred) {
   Image tmp(in.width(), in.height());

for (int y = 0; y < in.height(); y++)
   for (int x = 0; x < in.width(); x++)
     tmp(x, y) = (in(x-1, y) + in(x, y) + in(x+1, y))/3;

for (int y = 0; y < in.height(); y++)
   for (int x = 0; x < in.width(); x++)
   blurred(x, y) = (tmp(x, y-1) + tmp(x, y) + tmp(x, y+1))/3;
}</pre>
```

3x3 convolution (work efficient, two-pass implementation)

~ 9.9 ms per pixel on a modern CPU

3x3 box blur

2X zoom view

Optimized C++ code: 3x3 image blur

Good: 10x faster: ~ 0.9 ms per pixel on a modern quad-core CPU Bad: specific to SSE, hard to tell whats going on at all!

```
void fast_blur(const Image &in, Image &blurred) {
                                                                           Multi-core execution
 _{m128i} one_third = _{mm}_{set1}_{epi16(21846);}
                                                                           (partition image vertically)
 #pragma omp parallel for
 for (int yTile = 0; yTile < in.height(); yTile += 32) {</pre>
  _{m128i} a, b, c, sum, avg;
  _m128i tmp[(256/8) * (32+2)];
                                                                           Modified iteration order:
  for (int xTile = 0; xTile < in width(); xTile += 256) {</pre>
   _m128i *tmpPtr = tmp;
                                                                           256x32 block-major iteration
   for (int y = -1; y < 32+1; y++) {
                                                                           (to maximize cache hit rate)
    const uint16_t *inPtr = &(in(xTile, yTile+y));
    for (int x = 0; x < 256; x += 8) {
     a = _{mm}loadu_si128((_{m128i}*)(inPtr-1));
     b = _mm_loadu_si128((_m128i*)(inPtr+1));
     c = _{mm}load_si128((_{m}128i*)(inPtr));
                                                                              use of SIMD vector intrinsics
     sum = _mm_add_epi16(_mm_add_epi16(a, b), c);
     avg = _mm_mulhi_epi16(sum, one_third);
     _mm_store_si128(tmpPtr++, avg);
     inPtr += 8;
   tmpPtr = tmp;
   for (int y = 0; y < 32; y++) {
                                                                              two passes fused into one:
    _m128i *outPtr = (_m128i *)(&(blurred(xTile, yTile+y)));
    for (int x = 0; x < 256; x += 8) {
                                                                              tmp data read from cache
     a = _{mm}load_{si128}(tmpPtr+(2*256)/8);
     b = _{mm}load_si128(tmpPtr+256/8);
     c = _mm_load_si128(tmpPtr++);
                                                                    Note: this implementation recomputes
     sum = _mm_add_epi16(_mm_add_epi16(a, b), c);
     avg = _mm_mulhi_epi16(sum, one_third);
                                                                    intermediate values. Why?
      _mm_store_si128(outPtr++, avg);
}}}}
```

Halide blur

- Halide = two domain-specific co-languages
 - 1. A purely functional DSL for defining image processing algorithms
 - 2. A DSL for defining "schedules" for how to map these algorithms to a machine

```
Func halide_blur(Func in)

Algorithms are a series of functions (think: pipeline stages)

Func tmp, blurred;

Var x, y, xi, yi;

Functions (side-effect-free) map coordinates to values

(in, tmp and blurred are functions)

tmp(x, y) = (in(x-1, y) + in(x, y) + in(x+1, y))/3;

blurred(x, y) = (tmp(x, y-1) + tmp(x, y) + tmp(x, y+1))/3;
```

```
return blurred;
```

NOTE: execution order and storage are unspecified by the abstraction. Implementation can evaluate, reevaluate, cache individual points as desired!

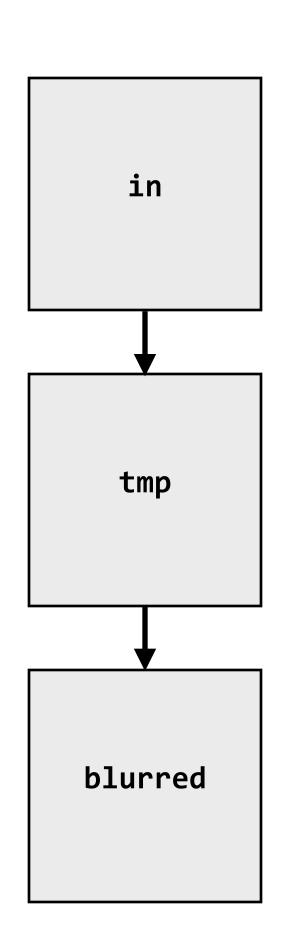

Images are pure functions from integer coordinates (up to

Halide program as a pipeline

```
Func halide_blur(Func in) {
  Func tmp, blurred;
  Var x, y, xi, yi;

// The algorithm
  tmp(x, y) = (in(x-1, y) + in(x, y) + in(x+1, y))/3;
  blurred(x, y) = (tmp(x, y-1) + tmp(x, y) + tmp(x, y+1))/3;

return blurred;
}
```

Halide blur

- Halide = two domain-specific co-languages
 - 1. A purely functional DSL for defining image processing algorithms
 - 2. A DSL for defining "schedules" for how to map these algorithms to a machine

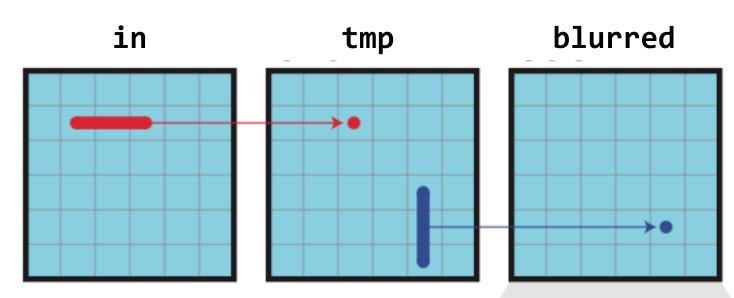

```
Func halide_blur(Func in) {
 Func tmp, blurred;
 Var x, y, xi, yi;
 // The algorithm
 tmp(x, y) = (in(x-1, y) + in(x, y) + in(x+1, y))/3;
 blurred(x, y) = (tmp(x, y-1) + tmp(x, y) + tmp(x, y+1))/3;
 // The schedule
 blurred.tile(x, y, xi, yi, 256, 32) __
                                                            When evaluating blurred, use 2D tiling order
         .vectorize(xi, 8).parallel(y);
                                                            (loops named by x, y, xi, yi). Use tile size 256 x 32.
 tmp.chunk(x).vectorize(x, 8);
                                                            Vectorize the xi loop (8-wide), use threads to
 return blurred;
                                                            parallelize the y loop
                                                           - Produce only chunks of tmp at a time. Vectorize
                                                            the x (innermost) loop
```

Separation of algorithm from schedule

- Key idea: separate specification of image processing algorithm (machine independent) from specification of schedule (machine-dependent mapping)
- Given algorithm and schedule description, Halide generates very high quality code for a target machine
 - Domain scope:
 - All computation over regular (up to 4D) grids
 - Only feed-forward pipelines (includes special support for reductions and fixed recursion depth)
 - All dependencies are inferable by compiler

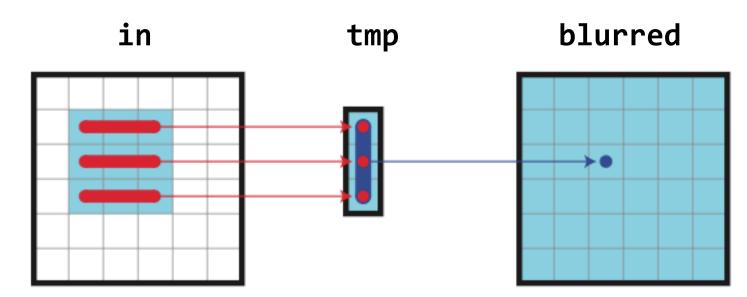

Halide schedule: producer/consumer scheduling

- Four basic scheduling primitives shown below
- Fifth primitive: "reuse" not shown

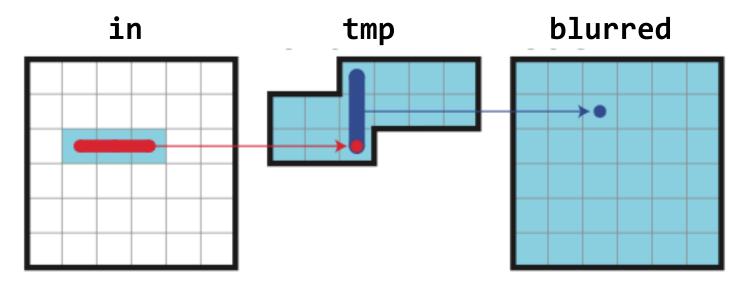

breadth first: each function is entirely evaluated before the next one.

"Root"

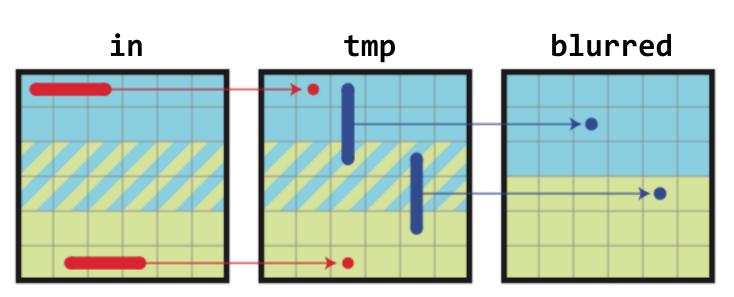

total fusion: values are computed on the fly each time that they are needed.

"Inline"

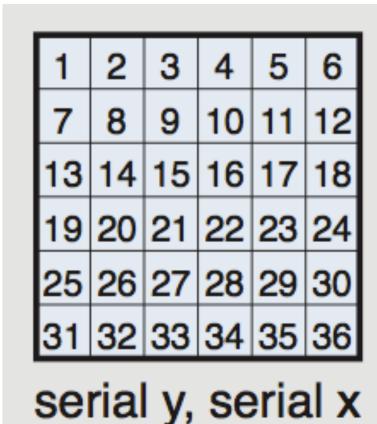

sliding window: values are computed when needed then stored until not useful anymore. "Sliding Window"

tiles: overlapping regions are processed in parallel, functions are evaluated one after another.

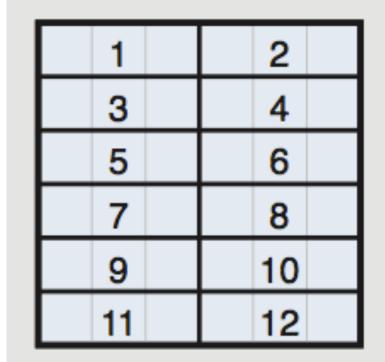

"Chunked"

Halide schedule: domain iteration

3	9	15	21	27	33			
4	10	16	22	28	34			
5	11	17	23	29	35			
6	12	18	24	30	36			
serial x, serial y								

Specify both order and how to parallelize (multi-thread, SIMD vector)

serial y vectorized x

parallel y vectorized x

1	2	5	6	9	10
3	4	7	8	11	12
13	14	17	18	21	22
15	16	19	20	23	24
25	26	29	30	33	34
27	28	31	32	35	36

split x into $2x_o + x_i$, split y into $2y_o + y_i$, serial y_o , x_o , y_i , x_i

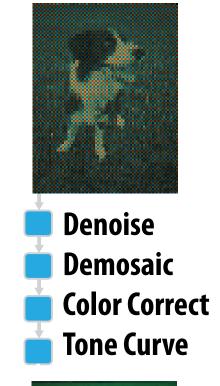

2D blocked iteration order

Halide results

Camera RAW processing pipeline

(Convert RAW sensor data to RGB image)

- Original: 463 lines of hand-tuned ARM assembly
- Halide: 2.75x less code, 5% faster

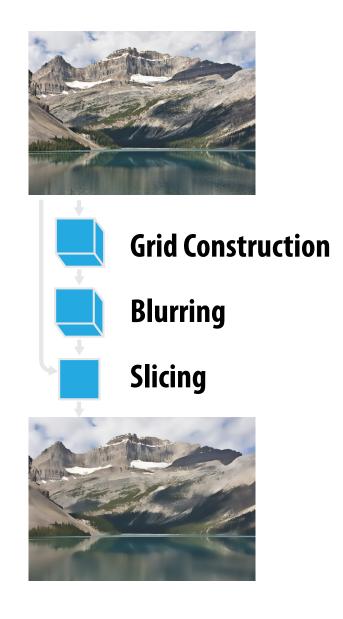

Bilateral filter

(Common image filtering operation used in many applications)

- Original 122 lines of C++
- Halide: 34 lines algorithm + 6 lines schedule
 - CPU implementation: 5.9x faster
 - GPU implementation: 2x faster than hand-written CUDA

Takeaway: Halide is not magic, but its abstractions allow rapid exploration of optimization space, allowing programmer to reach optimal points quickly

Many other recent domain-specific programming systems

Less domain specific than examples given today, but still designed specifically for: data-parallel computations on big data for distributed systems ("Map-Reduce")

DSL for graph-based machine learning computations

Also see **Green-Marl**(another DSL for describing operations on graphs)

Model-view-controller paradigm for web-applications

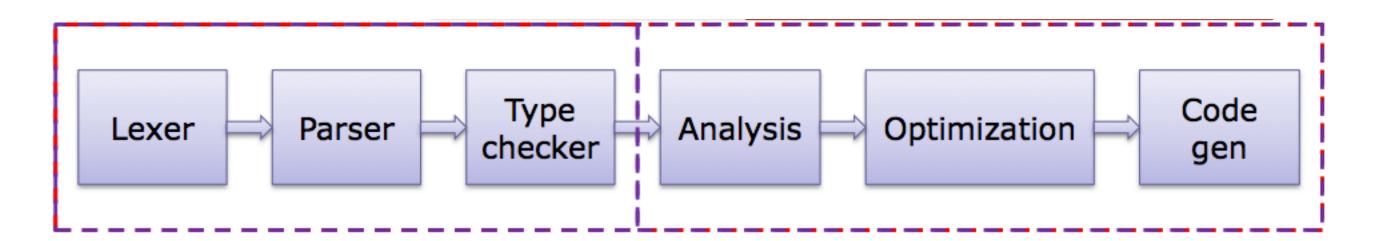

Ongoing efforts in many domains...

Domain-specific programming system development

- Can develop DSL as a stand-alone language
 - Graphics shading languages
 - MATLAB, SQL
- "Embed" DSL in an existing generic language
 - e.g., C++ library (GraphLab, OpenGL host-side API, Map-Reduce)
 - Lizst syntax above was all valid Scala code
- Active research idea:
 - Design generic languages that have facilities that assist rapid embedding of new domain-specific languages

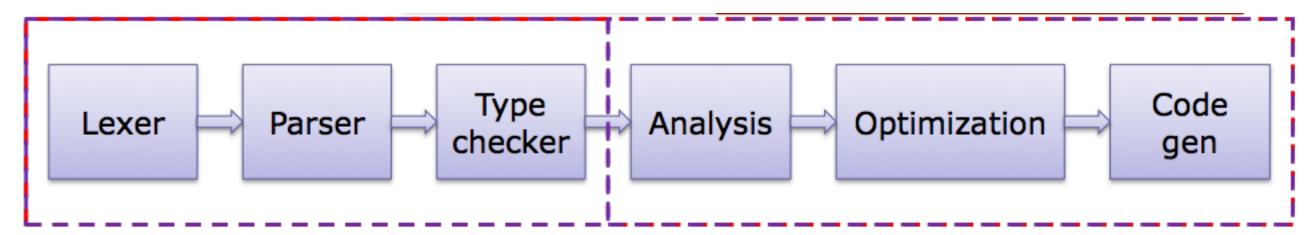

Facilitating development of new domain-specific languages

"Embed" domain-specific language in generic, flexible embedding language (Stand-alone domain-special language must implement everything from scratch)

Typical Compiler

"Modular staging" approach:

Domain language adopts front end from highly expressive embedding language

Leverage techniques like operator overloading, modern OOP (traits), type inference, closures, to make embedding language syntax appear native:

Liszt code shown before was actually valid Scala!

But customizes intermediate representation (IR) and participates in backend optimization and code-generation phases (exploiting domain knowledge while doing so)

Summary

- Modern machines: parallel, heterogeneous
 - Only way to increase compute capability in power-constrained world
- Most software uses very little of peak capability of machine
 - Very challenging to tune programs to these machines
 - Tuning efforts are not portable across machines
- Domain-specific programming environments trade-off generality to achieve productivity, performance, and portability
 - Case studies today: Liszt, Halide, OpenGL (see bonus slides)
 - Common trait: languages provide abstractions that make dependencies known
 - Understanding dependencies is necessary but not sufficient: need domain restrictions and domain knowledge for system to synthesize efficient implementations

Bonus slides! DSL Example 3:

OpenGL: a domain-specific system for 3D rendering

OpenGL graphics pipeline

Key abstraction: the graphics pipeline Graphics pipeline defines a basic program structure and data flows Programmable stages (red boxes): programmer fills in the body of o 3 the "for all" loops ° 1 **04** (pipeline stage executes "for all" primitives in input stream) **Vertices in 3D space** (provided by application) **Vertex stream Vertex Processing Triangles positioned on screen Triangle stream Fragment Generation** (Rasterization) **Fragment stream** "Fragments" (one fragment per each covered pixel per triangle) **Fragment Processing Shaded fragments Fragment stream Pixel Blend Operations Output image (pixels)**

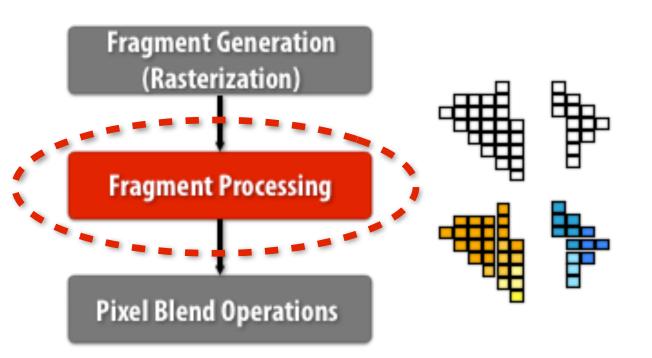

Fragment "shader" program

HLSL shader program: defines behavior of fragment processing stage Executes once per pixel covered by each triangle

Input: a "fragment": information about the triangle at the pixel Output: RGBA color (float4 datatype)

```
sampler mySamp;
Texture2D<float3> myTex;
float3 lightDir;

float4 diffuseShader(float3 norm, float2 uv)
{
   float3 kd;
   kd = myTex.sample(mySamp, uv);
   kd *= clamp(dot(lightDir, norm), 0.0, 1.0);
   return float4(kd, 1.0);
}
```

Productivity:

- SPMD program: no explicit parallelism
- Implicit parallelism: programmer writes no loops over fragments (think of shader as a loop body)
- Code runs independently for each input fragment (no loops = impossible to express a loop dependency)

Performance:

- SPMD program compiles to wide SIMD processing on GPU
- Work for many fragments dynamically balanced onto GPU cores
- Performance Portability:
 - Scales to GPUs with different # of cores
 - SPMD abstraction compiles to different SIMD widths (NVIDIA=32, AMD=64,

Special language primitive for texture mapping

```
sampler mySamp;
Texture2D<float3> myTex;
float3 lightDir;

float4 diffuseShader(float3 norm, float2 uv)
{
   float3 kd;
   kd = myTex.sample(mySamp, uv);
   kd *= clamp(dot(lightDir, norm), 0.0, 1.0);
   return float4(kd, 1.0);
}
```

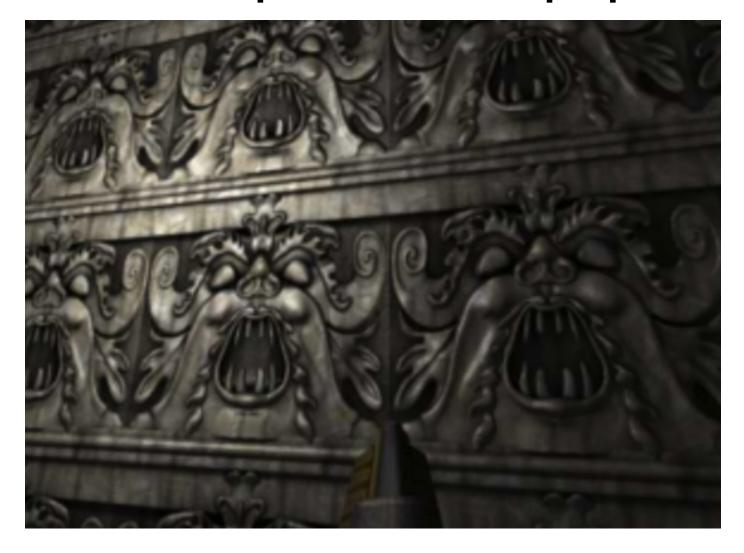

myTex:
NxN texture buffer

uv = (0.3, 0.5)

Intuitive abstraction: represents a texture lookup like an array access with a 2D floating point index.

Texture fetch semantics: sample from myTex at coordinate uv and filter using scheme (e.g., bilinear filtering) defined by mySamp.

Result of mapping texture onto plane, viewed with perspective

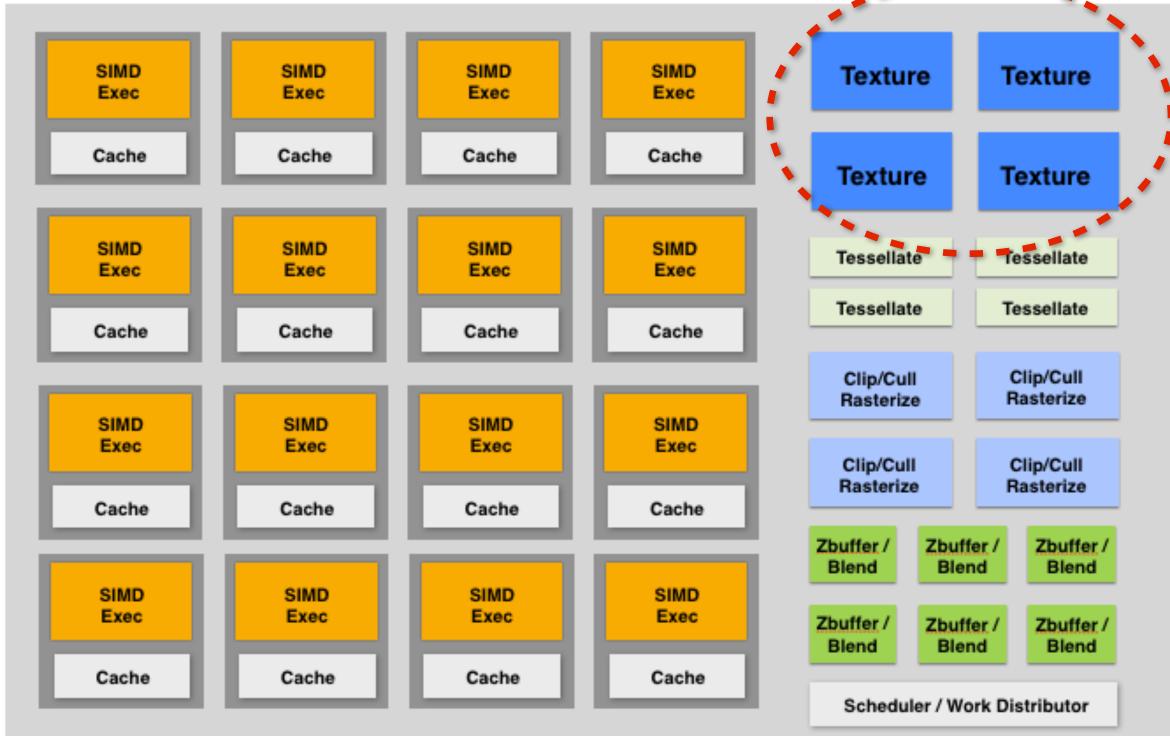

Texture mapping is expensive (and performance

- Texture mapping is a filtering operation (more than an array lookup: see 15-462)
 - If implemented in software: ~ 50 instructions, multiple conditionals
 - Read at least 8 values from texture map, blend them together
 - Unpredictable data access, little temporal locality
- Typical shader program performs multiple texture lookups
- Texture mapping is one of the most computationally demanding AND bandwidth intensive aspects of the graphics pipeline
 - Resources for texturing must run near 100% efficiency

Performance: texture mapping

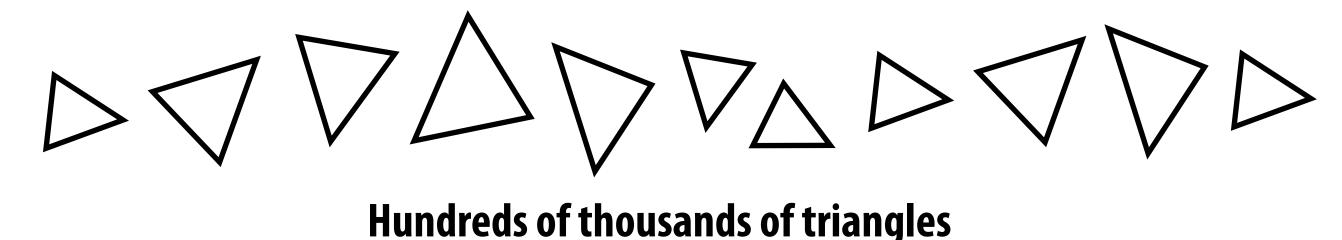

- Highly multi-threaded cores hide latency of memory access (texture primitive = source of long memory stalls is explicit in programming model)
- Fixed-function HW to perform texture mapping math
- Snecial-cache designs to canture reuse exploit read-only access to texture data

Performance: global application orchestration

Fragment Generation Fragment Pixel Blend

Millions of shaded fragments to blend into output image

Efficiently scheduling all this parallel work onto the GPU's heterogeneous pool of resources (while also respecting the ordering requirements of the OpenGL programming model) is challenging.

Each GPU vendor uses its own custom strategy (high-level abstraction allows for different implementations)

OpenGL summary

Productivity:

- High-level, intuitive abstractions (taught to undergrads in intro graphics class)
- Application implements kernels for triangles, vertices, and fragments
- Specific primitives for key functions like texture mapping

Portability

- Runs across wide range of GPUs: low-end integrated, high-end discrete, mobile
- Has allowed significant hardware innovation without impacting programmer

High-Performance

- Abstractions designed to map efficiently to hardware (proposed new features disallowed if they do not!)
- Encapsulating expensive operations as unique pipeline stages or built-in functions facilitates fixed-function implementations (texture, rasterization, frame-buffer blend)
- Utilize domain-knowledge in optimizing performance / mapping to hardware
 - Skip unnecessary work, e.g., if a triangle it is determined to be behind another, don't generate and shade its fragments
 - Non-overlapping fragments are independent despite ordering constraint
 - Interstage queues/buffers are sized based on expected triangle sizes
 - Use pipeline structure to make good scheduling decisions, set work priorities MU 15-418, Spring 2014
