“We kept thinking and brainstorming with our TAs, and then boom, a great 15-418 project idea just popped up out of nowhere.”

- Romy Madley Croft
Raising level of abstraction for synchronization

- **Machine-level atomic operations:**
  - Fetch-and-op, test-and-set, compare-and-swap, load linked-store conditional

- **We used these atomic operations to construct higher level synchronization primitives in software:**
  - Locks, barriers
  - We’ve seen how it can be challenging to produce correct programs using these primitives (easy to create bugs that violate atomicity, create deadlock, etc.)

- **Today: raising level of abstraction for synchronization even further:**
  - Idea: transactional memory
What you should know

- What a transaction is

- The difference (in semantics) between an atomic code block and lock/unlock primitives

- The basic design space of transactional memory implementations
  - Data versioning policy
  - Conflict detection policy
  - Granularity of detection

- The basics of a hardware implementation of transactional memory (consider how it relates to the cache coherence protocol implementations we’ve discussed previously in the course)
Review: ensuring atomicity via locks

void deposit(Acct account, int amount) {
    lock(account.lock);
    int tmp = bank.get(account);
    tmp += amount;
    bank.put(account, tmp);
    unlock(account.lock);
}

- Deposit is a read-modify-write operation: want “deposit” to be atomic with respect to other bank operations on this account
- Locks are one mechanism to synchronize threads to ensure atomicity of update (via ensuring mutual exclusion on the account)
Programming with transactions

void deposit(Acct account, int amount) {
    lock(account.lock);
    int tmp = bank.get(account);
    tmp += amount;
    bank.put(account, tmp);
    unlock(account.lock);
}

void deposit(Acct account, int amount) {
    atomic {
        int tmp = bank.get(account);
        tmp += amount;
        bank.put(account, tmp);
    }
}

- **Atomic construct is declarative**
  - Programmer states what to do (maintain atomicity of this code), not how to do it
  - No explicit creation or management of locks

- **System implements synchronization as necessary to ensure atomicity**
  - Implementation discussed today uses optimistic concurrency: serialization only in situations of true contention (R-W or W-W conflicts)
Declarative vs. imperative abstractions

- **Declarative:** programmer defines what should be done
  - Execute all these independent 1000 tasks
  - Perform this set of operations atomically

- **Imperative:** programmer states how it should be done
  - Spawn N worker threads. Assign work to threads by removing work from shared task queue
  - Acquire a lock, perform operations, release the lock
Transactional Memory (TM)

- **Memory transaction**
  - An atomic and isolated sequence of memory accesses
  - Inspired by database transactions

- **Atomicity (all or nothing)**
  - Upon transaction commit, all memory writes in transaction take effect at once
  - On transaction abort, none of the writes appear to take effect (as if transaction never happened)

- **Isolation**
  - No other processor can observe writes before commit

- **Serializability**
  - Transactions appear to commit in a single serial order
  - But the exact order of commits is not guaranteed by semantics of transaction
Motivating transactional memory
Another example: Java HashMap

Map: Key → Value
- Implemented as a hash table with linked list per bucket

```java
class HashEntry {
    Object key;
    Object value;
}

public class HashMap {
    private int size;
    private int bucketCount;
    private HashEntry[] buckets;

    public Object get(Object key) {
        int idx = hash(key); // compute hash
        HashEntry e = buckets[idx]; // find bucket
        while (e != null) { // find element in bucket
            if (equals(key, e.key))
                return e.value;
            e = e.next;
        }
        return null;
    }
}
```

Bad: not thread safe (when synchronization needed)
Good: no lock overhead when synchronization not needed
Synchronized HashMap

- Java 1.4 solution: synchronized layer
  - Convert any map to thread-safe variant
  - Uses explicit, coarse-grained locking specified by programmer

```java
public Object get(Object key) {
    synchronized (myHashMap) {
        // guards all accesses to hashMap
        return myHashMap.get(key);
    }
}
```

- Coarse-grain synchronized HashMap
  - Good: thread-safe, easy to program
  - Bad: limits concurrency, poor scalability
Review from earlier fine-grained sync lecture

What are better solutions for making hashmap object thread-safe?

```java
public Object get(Object key) {
    int idx = hash(key); // compute hash
    HashEntry e = buckets[idx]; // find bucket
    while (e != null) { // find element in bucket
        if (equals(key, e.key))
            return e.value;
        e = e.next;
    }
    return null;
}
```

- Use finer-grained synchronization: e.g., lock per bucket
  - Now thread safe: but incurs lock overhead even if synchronization not needed
Review: performance of fine-grained locking

Reduced contention leads to better performance

Balanced Tree

Hash-Table

Execution Time

Processors

coarse locks  
fine locks
Transactional HashMap

- Simply enclose all operation in atomic block
  - Semantics of atomic block: system ensures atomicity of logic within block

```java
public Object get(Object key) {
    atomic {
        // System guarantees atomicity
        return m.get(key);
    }
}
```

- Transactional HashMap
  - Good: thread-safe, easy to program
  - What about performance and scalability?
    - Depends on the workload and implementation (to be discussed)
Another example: tree update by two threads
Goal: modify nodes 3 and 4 in a thread-safe way

Slide credit: Austen McDonald
Fine-grained locking example
Goal: modify nodes 3 and 4 in a thread-safe way

Hand-over-hand locking
Fine-grained locking example
Goal: modify nodes 3 and 4 in a thread-safe way

Hand-over-hand locking
Fine-grained locking example
Goal: modify nodes 3 and 4 in a thread-safe way

Hand-over-hand locking

Locking can prevent concurrency
(here: locks on node 1 and 2 during update to node 3 could delay update to 4)
Transactions example

Figure highlights data touched as part of transaction

Transaction A
READ: 1, 2, 3
Transactions example

Figure highlights data touched as part of transaction

Transaction A
READ: 1, 2, 3
WRITE: 3
Transactions example

Figure highlights data touched as part of transaction

Transaction A
READ: 1, 2, 3
WRITE: 3

Transaction B
READ: 1, 2, 4
WRITE: 4

NO READ-WRITE or WRITE-WRITE conflicts!
(no transaction writes to data that is accessed by other transactions)

Slide credit: Austen McDonald
Transactions example #2
(Both transactions modify node 3)

Transaction A
READ: 1, 2, 3
WRITE: 3

Transaction B
READ: 1, 2, 3
WRITE: 3

Conflicts exist: transactions must be serialized
(both transactions write to node 3)
Performance: locks vs. transactions

“TCC” is a HW-based TM system

[Graphs showing execution time for different lock types (coarse, fine, and TCC) across varying numbers of processors for HashMap and Balanced Tree data structures.]
Failure atomicity: locks

```java
void transfer(A, B, amount) {
    synchronized(bank) {
        try {
            withdraw(A, amount);
            deposit(B, amount);
        } catch(exception1) { /* undo code 1*/ }
        catch(exception2) { /* undo code 2*/ }
    ...
    }
}
```

- Complexity of manually catching exceptions
  - Programmer provides “undo” code on a case-by-case basis
  - Complexity: must track what to undo and how...
  - Some side-effects may become visible to other threads
    - E.g., an uncaught case can deadlock the system...
null

Failure atomicity: transactions

```c
void transfer(A, B, amount)
{
    atomic {
        withdraw(A, amount);
        deposit(B, amount);
    }
}
```

- System now responsible for processing exceptions
  - All exceptions but those explicitly managed by the programmer
  - Transaction is aborted and updates are undone
  - No partial updates are visible to other threads
    - E.g., no locks held by a failing threads…
Composability: locks

void transfer(A, B, amount)
{
    synchronized(A) {
        synchronized(B) {
            withdraw(A, amount);
            deposit(B, amount);
        }
    }
}

Composing lock-based code can be tricky
- Requires system-wide policies to get correct
- Breaks software modularity

Programmer caught between an extra lock and a hard place
- Coarse-grain locks: low performance
- Fine-grain locking: good for performance, but can lead to deadlock

Thread 0:
transfer(x, y, 100)
Thread 1:
transfer(y, x, 100);
Composability: locks

Composing lock-based code can be tricky
- Requires system-wide policies to get correct
- Breaks software modularity

Programmer caught between an extra lock and a hard place
- Coarse-grain locks: low performance
- Fine-grain locking: good for performance, but can lead to deadlock

```java
class Example {
    void transfer(A, B, amount) {
        synchronized(A) {
            synchronized(B) {
                withdrwa(A, amount);
                deposit(B, amount);
            }
        }
    }

    void transfer2(A, B, amount) {
        synchronized(B) {
            synchronized(A) {
                withdrwa(A, 2*amount);
                deposit(B, 2*amount);
            }
        }
    }
}
```
void transfer(A, B, amount) {
    atomic {
        withdraw(A, amount);
        deposit(B, amount);
    }
}

Transactions compose gracefully
- Programmer declares global intent (atomic execution of transfer)
  - No need to know about global implementation strategy
- Transaction in transfer subsumes any defined in withdraw and deposit
  - Outermost transaction defines atomicity boundary

System manages concurrency as well as possible serialization
- Serialization for transfer(A, B, 100) and transfer(B, A, 200)
- Concurrency for transfer(A, B, 100) and transfer(C, D, 200)
Advantages (promise) of transactional memory

- Easy to use synchronization construct
  - As easy to use as coarse-grain locks
  - Programmer declares need for atomicity, system implements

- Often performs as well as fine-grained locks
  - Automatic read-read concurrency and fine-grained concurrency

- Failure atomicity and recovery
  - No lost locks when a thread fails
  - Failure recovery = transaction abort + restart

- Composability
  - Safe and scalable composition of software modules
Example integration with OpenMP

- **Example: OpenTM = OpenMP + TM**
  - OpenMP: master-slave parallel model
    - Easy to specify parallel loops and tasks
  - TM: atomic and isolation execution
    - Easy to specify synchronization and speculation

- **OpenTM features**
  - Transactions, transactional loops and transactional sections
  - Data directives for TM (e.g., thread private data)
  - Runtime system hints for TM

- **Code example:**
  ```c
  #pragma omp target schedule (static, chunk=50)
  for (int i=0; i<N; i++) {
    bin[A[i]]++;
  }
  ```
Atomic `{ }` ≠ lock() + unlock()

- The difference
  - Atomic: high-level declaration of atomicity
    - Does not specify implementation/blocking behavior
  - Lock: low-level blocking primitive
    - Does not provide atomicity or isolation on its own

- Keep in mind
  - Locks can be used to implement an atomic block but...
  - Locks can be used for purposes beyond atomicity
    - Cannot replace all uses of locks with atomic regions
  - Atomic eliminates many data races, but programming with atomic blocks can still suffer from atomicity violations: e.g., programmer erroneous splits sequence that should be atomic into two atomic blocks

Make sure you understand this difference in semantics!
What is the problem with replacing synchronized with atomic in this example?

// Thread 1
synchronized(lock1)
{
    ...
    flagA = true;
    while (flagB == 0);
    ...
}

// Thread 2
synchronized(lock2)
{
    ...
    flagB = true;
    while (flagA == 0);
    ...
}
Example: atomicity violation due to programmer error

- Programmer mistake: logically atomic code sequence (in thread 1) is erroneously separated into two atomic blocks (allowing another thread to set pointer to NULL in between)
**Transactional memory: summary + benefits**

- **TM = declarative synchronization**
  - User specifies requirement (atomicity and isolation)
  - System implements semantics in best possible way

- **Motivation for TM**
  - Difficult for programmers to get explicit synchronization right
    - Correctness vs. performance vs. complexity
  - Explicit synchronization is difficult to scale
    - Locking scheme for four CPUs is often not the best scheme for 64 CPUs
  - Explicit synchronization can break composability of software
    - Need a globally-adhered to locking policy
  - Other advantages: fault atomicity, ...

- **Productivity argument for transactional memory:**
  - System support for transactions can achieve 90% of the benefit of programming with fined-grained locks, with 10% of the development time
Implementing transactional memory
Recall: transactional memory

- Atomicity (all or nothing)
  - At commit, all memory writes take effect at once
  - In event of abort, none of the writes appear to take effect

- Isolation
  - No other code can observe writes before commit

- Serializability
  - Transactions seem to commit in a single serial order
  - The exact order is not guaranteed though
TM implementation basics

- TM systems must provide atomicity and isolation
  - Without sacrificing concurrency

- Basic implementation requirements
  - Data versioning (ALLOWS abort)
  - Conflict detection and resolution (WHEN to abort)

- Implementation options
  - Hardware transactional memory (HTM)
  - Software transactional memory (STM)
  - Hybrid transactional memory
    - e.g., hardware-accelerated STMs
Data versioning

Manage uncommitted (new) and previously committed (old) versions of data for concurrent transactions

1. Eager versioning (undo-log based)

2. Lazy versioning (write-buffer based)
Eager versioning

Update memory immediately, maintain “undo log” in case of abort

**Begin Transaction**

- Thread (executing transaction)
- Memory: X: 10
- Undo log

**Write x←15**

- Thread (executing transaction)
- Memory: X: 15
- Undo log: X: 10

**Commit Transaction**

- Thread (executing transaction)
- Memory: X: 15
- Undo log: X: 10

**Abort Transaction**

- Thread (executing transaction)
- Memory: X: 10
- Undo log: X: 10
Lazy versioning

Log memory updates in transaction write buffer, flush buffer on commit

Begin Transaction

Thread (executing transaction)

Write buffer

X: 10
Memory

Write x←15

Thread (executing transaction)

Write buffer

X: 15

Commit Transaction

Thread (executing transaction)

X: 15
Memory

Abort Transaction

Thread (executing transaction)

Write buffer

X: 15

X: 10
Memory
Data versioning

- Manage uncommitted (new) and committed (old) versions of data for concurrent transactions

- **Eager versioning (undo-log based)**
  - Update memory location directly on write
  - Maintain undo information in a log (incurs per-store overhead)
  - Good: faster commit (data is already in memory)
  - Bad: slower aborts, fault tolerance issues (consider: crash in middle of transaction)

- **Lazy versioning (write-buffer based)**
  - Buffer data in a write buffer until commit
  - Update actual memory location on commit
  - Good: faster abort (just clear log), no fault tolerance issues
  - Bad: slower commits

Eager versioning philosophy: “write to memory immediately, hoping transaction won’t abort” (but deal with aborts when you have to)

Lazy versioning philosophy: “only write to memory when you have to.”
Conflict detection

- **Must detect and handle conflicts between transactions**
  - Read-write conflict: transaction A reads address X, which was written to by pending transaction B
  - Write-write conflict: transactions A and B are both pending, and both write to address X.

- **System must track a transaction’s read set and write set**
  - Read-set: addresses read within the transaction
  - Write-set: addresses written within transaction
Pessimistic detection

- Check for conflicts during loads or stores
  - A HW implementation will check for conflicts through coherence actions (will discuss in further later)
  - Philosophy: “I suspect conflicts might happen, so let’s always check to see if one has occurred after each memory operation... if I’m going to have to roll back, let’s do it now to avoid wasted work.”

- “Contention manager” decides to stall or abort transaction when a conflict is detected
  - Various priority policies to handle common case fast
Pessimistic detection examples

Case 1: Success
- Time: T0 → T1
  - rd A
  - wr B
  - wr C
  - commit
  - check

Case 2: Early detect (and stall)
- Time: T0 → T1
  - wr A
  - check
  - rd A
  - check
  - stall

Case 3: Abort
- Time: T0 → T1
  - rd A
  - check
  - wr A
  - check
  - restart
  - rd A
  - check
  - restart
  - stall (case 2)
  - commit

Case 4: No progress
- Time: T0 → T1
  - wr A
  - check
  - wr A
  - check
  - restart
  - restart
  - restart
  - wr A

(Note: diagrams assume “aggressive” contention manager on writes: writer wins)

CMU 15-418/618, Spring 2015
Optimistic detection

Detect conflicts when a transaction attempts to commit
- HW: validate write set using coherence actions
  - Get exclusive access for cache lines in write set
  - Intuition: “Let’s hope for the best and sort out all the conflicts only when the transaction tries to commit.”

On a conflict, give priority to committing transaction
- Other transactions may abort later on
- On conflicts between committing transactions, use contention manager to decide priority

Note: can use optimistic and pessimistic schemes together
- Several STM systems use optimistic for reads and pessimistic for writes
Optimistic detection

Case 1
- T0: rd A, wr B, wr C
- T1: commit

Success

Case 2
- T0: rd A, wr A
- T1: commit

Abort

Case 3
- T0: rd A
- T1: wr A, commit

Success

Case 4
- T0: rd A
- T1: wr A, commit

Forward Progress

Time
Conflict detection trade-offs

- **Pessimistic conflict detection (a.k.a. “eager”)**
  - Good: Detect conflicts early (undo less work, turn some aborts to stalls)
  - Bad: no forward progress guarantees, more aborts in some cases
  - Bad: fine-grained communication (check on each load/store)
  - Bad: detection on critical path

- **Optimistic conflict detection (a.k.a. “commit” or “lazy”)**
  - Good: forward progress guarantees
  - Good: potentially less conflicts, bulk communication
  - Bad: detects conflicts late, can still have fairness problems
Conflict detection granularity

- Object granularity (SW-based techniques)
  - Good: reduced overhead (time/space)
  - Good: close to programmer’s reasoning
  - Bad: false sharing on large objects (e.g. arrays)

- Machine word granularity
  - Good: minimize false sharing
  - Bad: increased overhead (time/space)

- Cache-line granularity
  - Good: compromise between object & word

- Can mix and match to get best of both worlds
  - Word-level for arrays, object-level for other data, …
TM implementation space (examples)

- **Hardware TM systems**
  - Lazy + optimistic: Stanford TCC
  - Lazy + pessimistic: MIT LTM, Intel VTM
  - Eager + pessimistic: Wisconsin LogTM
  - Eager + optimistic: not practical

- **Software TM systems**
  - Lazy + optimistic (rd/wr): Sun TL2
  - Lazy + optimistic (rd)/pessimistic (wr): MS OSTM
  - Eager + optimistic (rd)/pessimistic (wr): Intel STM
  - Eager + pessimistic (rd/wr): Intel STM

- **Optimal design remains an open question**
  - May be different for HW, SW, and hybrid
Hardware transactional memory (HTM)

- Data versioning is implemented in caches
  - Cache the write buffer or the undo log
  - Add new cache line metadata to track transaction read set and write set

- Conflict detection through cache coherence protocol
  - Coherence lookups detect conflicts between transactions
  - Works with snooping and directory coherence

- Note:
  - Register checkpoint must also be taken at transaction begin (to restore execution context state on abort)
HTM design

- Cache lines annotated to track read set and write set
  - R bit: indicates data read by transaction (set on loads)
  - W bit: indicates data written by transaction (set on stores)
    - R/W bits can be at word or cache-line granularity
  - R/W bits gang-cleared on transaction commit or abort
  - For eager versioning, need a 2nd cache write for undo log

Coherence requests check R/W bits to detect conflicts
- Shared request to W-word is a read-write conflict
- Exclusive request to R-word is a write-read conflict
- Exclusive request to W-word is a write-write conflict
Example HTM implementation: lazy-optimistic

- CPU changes
  - Ability to checkpoint register state (available in many CPUs)
  - TM state registers (status, pointers to handlers, …)
Example HTM implementation: lazy-optimistic

- **Cache changes**
  - R bit indicates membership to read set
  - W bit indicates membership to write set
**HTM transaction execution**

- **Transaction begin**
  - Initialize CPU and cache state
  - Take register checkpoint

**HTM transaction execution**

- Xbegin
- Load A
- Load B
- Store C ← 5
- Xcommit
**HTM transaction execution**

- **Load operation**
  - Serve cache miss if needed
  - Mark data as part of read set

```
Xbegin
  Load A  ←
  Load B
  Store C ← 5
Xcommit
```
HTM transaction execution

Xbegin
  Load A
  Load B
  Store C ⇐ 5
Xcommit

Load operation
  - Serve cache miss if needed
  - Mark data as part of read set
**HTM transaction execution**

- **Store operation**
  - Service cache miss if needed
  - Mark data as part of write set (note: this is not a load into exclusive state. Why?)

![Diagram](image)

Xbegin
Load A
Load B
Store C ← 5
Xcommit
HTM transaction execution: commit

- **Xbegin**
  - Load A
  - Load B
  - Store C ← 5
- **Xcommit** ←

**Cache**

<table>

**Fast two-phase commit**

- **Validate**: request exclusive access to write set lines (if needed)
- **Commit**: gang-reset R and W bits, turns write set data to valid (dirty) data

**upgradeX C**
(result: C is now in exclusive, dirty state)
HTM transaction execution: detect/abort

Assume remote processor commits transaction with writes to A and D

- **Xbegin**
  - Load A
  - Load B
  - Store C ← 5

- **Xcommit**

**Fast conflict detection and abort**

- Check: lookup exclusive requests in the read set and write set
- Abort: invalidate write set, gang-reset R and W bits, restore to register checkpoint

(coherence requests from another core’s commit)

(remote core’s write of A conflicts with local read of A: triggers abort of pending local transaction)
Hardware transactional memory support in Intel Haswell architecture *

- New instructions for “restricted transactional memory” (RTM)
  - `xbegin`: takes pointer to “fallback address” in case of abort
    - e.g., fallback to code-path with a spin-lock
  - `xend`
  - `xabort`
  - Implementation: tracks read and write set in L1 cache

- Processor makes sure all memory operations commit atomically
  - But processor may automatically abort transaction for many reasons (e.g., eviction of line in read or write set will cause a transaction abort).
    - Implementation does not guarantee progress (see fallback address)
  - Intel optimization guide (ch 12) gives guidelines for increasing probability that transactions will not abort

* Shipped with bug that caused Intel disable it when discovered in 2014, supposedly fixed in Broadwell arch chips
Summary: transactional memory

- Atomic construct: declaration of atomic behavior
  - Motivating idea: increase simplicity of synchronization, without (significantly) sacrificing performance

- Transactional memory implementation
  - Many variants have been proposed: SW, HW, SW+HW
  - Implementations differ in:
    - Versioning policy (eager vs. lazy)
    - Conflict detection policy (pessimistic vs. optimistic)
    - Detection granularity

- Hardware transactional memory
  - Versioned data is kept in caches
  - Conflict detection mechanisms built upon coherence protocol
